Air Commodore J. KYLE (London, W.1) writes: I wish to invite your attention to the statement against my name in the Proceedings of Council reported in the *Supplement* of Jan. 22 (p. 33) to the effect that "so far as their terms of reference were concerned, a permanent Commission with pension was not visualized." The two points I made were that: (i) The new title of W.R.A.F. did not designate a separate service or corps with women's units, but those women enlisted or commissioned on a substitution basis, as applicable. (ii) Women doctors would be commissioned under exactly the same terms as their male colleagues except in two main, and one lesser, respect—i.e. (a) Women doctors would be commissioned into the W.R.A.F. as all other women, and (b) The commission, at the moment, would still be on a short-service basis only, as the question of permanent commissions and pensions had not yet been finalized; (c)—the lesser point—Rank titles, except in the first rank of Flying Officer, would be those at present in use in the W.A.A.F. I suggest that, as permanent commissions are visualized, but not so far finalized, owing to continuing discussion on scales of pension, the word is incorrect, and that you will as a minimum substitute the words "was not finalized" for the reported statement "was not visualized."

Association Notices

PROPOSED ALTERATION IN DENBIGH AND FLINT DIVISION

Notice is hereby given by the Council of a proposal to form two Divisions in the place of the present Denbigh and Flint Division as follows:

The East Denbigh and Flint Division: the area of the present Denbigh and Flint Division to the east of the Clwydian Range.

The West Denbigh and Flint Division: that part of the present Denbigh and Flint Division which lies to the west of the Clwydian Range, with the addition of Colwyn Bay, Old Colwyn, and Rhos-on-Sea.

Any member affected by this proposal and objecting thereto should write to the Secretary of the Association not later than Feb. 26, 1949.

CHARLES HILL,
Secretary.

SPECIAL REPRESENTATIVE MEETING

Notice is hereby given that on the requisition of the Council, and of a number of Constituencies exceeding 20 as prescribed by Bylaw 46 (1), a Special Representative Meeting of the British Medical Association will be held in the Great Hall, B.M.A. House, London, W.C.1, on Tuesday, March 29, 1949, at 10 a.m. The business of the meeting is to consider the question of remuneration to general practitioners under the National Health Service Acts.

CHARLES HILL,
Secretary.

By order of the Chairman of
the Representative Body.

SPECIAL REPRESENTATIVE MEETING

Notice is hereby given that on the requisition of the Council a Special Representative Meeting of the British Medical Association will be held in the Great Hall, B.M.A. House, London, W.C.1, on Wednesday, March 30, 1949, at 10 a.m. The business of the meeting is to consider a report and recommendations from the Council on the constitution of the Association.

CHARLES HILL,
Secretary.

By order of the Chairman of
the Representative Body.

Diary of Central Meetings

FEBRUARY

- 2 Wed. Subcommittee on Revision of Rates of Pay and Allowances 10.30 a.m.
- 2 Wed. Committee re constitutional position of Association, 2 p.m.
- 3 Thurs. Proprietary Medicines Committee, 2 p.m.
- 9 Wed. Health Education Subcommittee, 10.30 a.m.
- 10 Thurs. Journal Committee, 11 a.m.
- 14 Mon. Armed Forces Committee, 12 p.m.
- 15 Tues. War Memorial Committee, 11.30 a.m.
- 24 Thurs. Occupational Health Committee, 2 p.m.
- 24 Thurs. Committee on Psychiatry and the Law, 2 p.m.

MARCH

- 11 Fri. Public Health Committee, 2 p.m.

Branch and Division Meetings to be Held

HASTINGS DIVISION.—At Royal East Sussex Hospital, Tuesday, Feb. 1, 8.30 p.m. Mr. Lionel E. C. Norbury: "Cancer of the Rectum." To be illustrated by specimens and lantern slides.

LEWISHAM DIVISION.—At Lewisham Hospital, 390, High Street, London, S.E., Friday, Feb. 4, 8.30 p.m. Dr. D. Stafford Clark: "The More Interesting Aspects of Modern Psychological Medicine."

NORTH EAST SUFFOLK DIVISION.—At Lowestoft and North Suffolk Hospital, Sunday, Jan. 30, 3 p.m. Meeting open to all medical practitioners.

NUNEATON AND TAMWORTH DIVISION.—At Red Lion Hotel, Atherton, Tuesday, Feb. 1, 8.30 p.m. Dr. J. R. Owen: "Common Obstetric Difficulties."

RICHMOND DIVISION.—At Royal Hospital, Richmond, Tuesday, Feb. 1, 9 p.m. Agenda: (1) Lecture by Dr. Thomas F. Main: "Present Trends in the Treatment of Neurosis." (2) To consider resolution: "As the cost of living for medical practitioners has increased by at least 100% since 1938, that the profession should not agree to a betterment factor of less than 50%."

ST. PANCRAS DIVISION.—At B.M.A. House, Tavistock Square, London, W.C., Friday, Feb. 4, 8.30 p.m. "At Home" to members of neighbouring Divisions. Film: "Angina Pectoris," by Dr. Joseph E. F. Riseman. Dr. George E. S. Ward will open a discussion following the film.

Meetings of Branches and Divisions

BRIGHTON DIVISION

The Division held their annual ball at Hove on Dec. 17, 1948. The proceeds amounted to the sum of £233 12s. 11d., and a cheque for this amount has been sent to the Royal Medical Benevolent Fund.

TUBERCULOSIS AT THE CROSSROADS*

BY

C. O. STALLYBRASS, M.D., D.P.H.

Formerly Lecturer in Public Health Administration, University of Liverpool

Tuberculosis was described by Bunyan as "Captain of the men of Death." Perhaps the most important fact about tuberculosis is that it no longer holds that pre-eminent title. But it is still the main killer of youth in its prime, and causes in this country nearly one-third of the deaths between the ages of 15 and 39 and a total of 24,000 per annum at all ages. As a cause of death phthisis has been declining throughout the period since deaths were first registered and classified in 1838—i.e., nine years before the appointment of Dr. Duncan as first medical officer of health in Liverpool (Ransome, 1915). The decline has been remarkably continuous and steady since that date, though fluctuations are noticed at times, epidemics of influenza (e.g., 1890) and the two world wars being occasional causes of temporary rises. Generally when these events had passed the decline continued as before. What, then, has been the major cause of its decline? It is chastening to take the long view in this matter.

Tuberculosis mortality, like infantile mortality, has always been regarded as one of the best indices of the sanitary well-being of a community. The causes of the great reduction of infantile mortality are complex, and it is not easy to give each factor its appropriate weight. May not the causation of the fall of tuberculosis mortality be likewise complex? Certainly to regard this mortality rate as a sensitive sanitary index is a clear indication that we consider the reasons for its fall to be complex.

In 1847 the English mortality from phthisis was 3,189 per million, and the female mortality was higher than the male; nearly a century later the standardized death rate was 528 per million—i.e., one-sixth of what it was in 1847—and the female mortality was 53% of that of the males.

Tuberculosis Mortality in Infancy

The ages at death also show some striking differences. In 1860 18% of the deaths from tuberculosis in Liverpool were at ages under 5 years; and in 1880 the proportion was 32%; in 1946 the proportion was 6.5%, or only about one-fifth of the 1880 figure. It is, however, reasonable to ask whether all the infantile deaths ascribed to tuberculosis in 1880 were in reality so caused. One may question the significance of diagnoses such as *tabes mesenterica*, and be in doubt whether that title did not include deaths from prematurity, marasmus, enteritis, etc. If we consider deaths from tuberculous meningitis we find that equally important changes have been taking place, more especially in infancy and childhood. I have obtained from the Registrar-General, and have taken out from the Liverpool records, the deaths at ages under 1, 1 to 5, 5 to 10, and so on up to 25 years of age, since 1915. One of the difficulties in investigating tuberculosis records is to be sure that one is dealing with comparable statistics, and it is for that reason that the

figures go back to only 1915; before then differences both of nomenclature and of tabulation would gravely complicate comparisons. What is shown, however, is remarkable. In Liverpool the crude mortality during the first year of life in 1947 was only 9% of that recorded in 1915; in the next four years of life it was 18%, from 5 to 10 years 26%, from 10 to 15 years 40%, and at higher ages the reduction is smaller. But the total phthisis mortality has only been halved in these twenty-eight years. Similar, though not so pronounced, reductions in the deaths of infants ascribed to tuberculous meningitis have occurred in England and Wales. The higher the total tuberculosis mortality the greater the proportionate reduction in the meningeal fraction of that total. In the middle of last century many deaths of infants were ascribed to acute hydrocephalus or to cephalitis, the word meningitis seldom being used.

What is the significance of this rapid reduction in tuberculo-meningitic mortality? Tuberculous meningitis ensues when a tuberculoma in the brain or meninx infects the water-bath in which the brain lies; the tuberculoma in this case is the result of a blood-borne infection arising, as a rule, in a primary infection. It would appear, then, that this very rapid reduction in meningeal deaths results from a quite considerable reduction in infection of infants with the human bacillus, or at least of massive infection. That this rapid rate of reduction follows upon the passing of the National Insurance Act, 1911, and the inception of sanatorium benefit and the setting up of tuberculosis departments generally may be no coincidence. In Denmark in 1945 only 28 deaths from tuberculous meningitis took place, of which four were in Copenhagen. This observation may be a valuable clue in the tuberculosis labyrinth. One thing is sure: it bears little or no relation to the improvement of milk supplies or the pasteurization of milk. The case for these as preventive of tuberculous peritonitis and of bone and joint disease needs no further comment; it has been adequately presented by Wilson (1942) and is conclusive. Every case of tuberculous meningitis in childhood should be regarded as a pointer to a dangerous open case of respiratory tuberculosis in the immediate *entourage* of the sick infant; this case should at once be sought and the appropriate action taken when found.

In comparison with a guinea-pig, man is resistant to attack by the tubercle bacillus. He cannot presumably be infected by a single bacillus as can the cavy. Every overt case of tuberculosis is an example of a breakdown of resistance. Repeated massive doses of infection, especially in infancy, provide one of the methods by which that resistance is overcome. Any measures which tend to reduce or prevent such massive infections will be preventive of tuberculosis—the disease that kills and maims. I have used the tuberculo-meningitic mortality as a possible index of a reduction in massive infection; other evidence will appear later. But, regarding the continuous decline in phthisis mortality for over a century, even with the greatest regard

*A paper read at the North-Western Branch of the Society of Medical Officers of Health on Nov. 12, 1948.

for the sanitary achievements of Duncan and his successors we cannot think of sanitation as the major factor in the reduction.

Social and Economic Factors in Tuberculosis Causation

We must accordingly seek for a cause for the reduction in some more general factor of social amelioration which would affect the resistance of the mass of the population; for the general occurrence of infection within the first twenty years of life—at least of *urban* life—is widely recognized. This belief is based primarily on the findings of Naegeli (1900) in Zurich and of Burkhardt (1906) in Dresden. Naegeli found evidence of tuberculosis in 17% of necropsy examinations in those under 18 years of age; but in those over 18 years old the proportion was 93%. Burkhardt found the proportions in the same two age groups to be 38% and 91% respectively. When the use of the cutaneous tuberculin reaction was applied by von Pirquet (1911) to children in Vienna in 1909 he found that in the age group 13–14 years no less than 91% of the children reacted positively. These results relate to urban populations. The Prophit Survey (1948), applying the Mantoux reaction to student nurses from Wales and Ireland upon entry into hospital, found 26% negative reactions as against 18% negative amongst English nurses. In England there was only a small difference between the percentages of negative reactors among nurses of urban (18%) and rural (20%) provenance, but in Wales and Ireland the proportions were 19% and 35% respectively. It is evident that in recent years in the rural parts of the British Isles, more especially Wales and Ireland, infection with tuberculosis has by no means been universal, even if we take into consideration that a proportion of the negative reactions may once have been weakly positive and have subsequently reverted. Among London medical students only 14% were *negative*; in students in some universities in the United States the proportion is reversed and only 10–15% were *positive*.

Some economists have used the price of wheat as an index of nutrition, and a close correlation was found in some countries, notably Germany, between this figure and that of the phthisis mortality; but Sir Arthur Newsholme pointed out that in France and Ireland there was no such parallelism. This is not surprising, for money is constantly changing its value in relation to goods.

When for the price of wheat we substitute the "real value of wages"—i.e., what you can get with the money you earn—as was done by Ewart in 1923, there is revealed a remarkably close inverse correlation during the period 1851 to 1915 in England and Wales. Malnutrition and famine have again and again been shown to be productive of a rise in tuberculosis mortality. The 1914–18 war appeared to indicate fat shortage as productive of a rise in deaths from phthisis; the rise was earliest and greatest in blockaded Germany, later and smaller in Great Britain, where U-boat warfare limited imports, and latest and least in the United States, where the shortage was least felt. Shortage of fat-soluble vitamins was present in greater or lesser degree, but Danish and Swedish experiences negative a shortage of vitamin A as the main factors in the increase. There was also a shortage of first-class proteins according to Faber (1938), and he regarded this as the more important. It is not practicable to pin the effects of malnutrition to the deficiency of one ingredient of the diet. The part played by fatigue in the liability to develop clinical tuberculosis in wartime must not be overlooked (M.R.C., 1942).

During the 1939–45 war the rise in deaths from tuberculous meningitis and in young adults in this country pointed to factors other than nutrition being operative, and the

increased exposure to infection in air-raid shelters or elsewhere appears to have been a major cause. This rise reinforces the belief that a high proportional rate of mortality from meningitis indicates a high degree of massive infection in infancy and childhood.

The real value of wages gives a measure of the capacity of the average citizen to acquire goods, but it does not indicate how this capacity is distributed among the population or on what goods it is expended. The Registrar-General's figures show the heaviest incidence of tuberculosis to be upon the lowest-paid workers—i.e., social Class V—whose tuberculosis mortality is double that of the professional Class I.

Numerous coefficients have been calculated (see especially Hart and Wright, 1939) which show a significant high association of tuberculosis mortality on the one hand and poverty, pauperism, substandard housing, and overcrowding on the other. Hart and Wright applied the method of partial correlation,* which endeavours to weight the several possible factors taken into consideration. The significance of overcrowding appeared to be increasing. There can be no doubt that poverty is closely associated with tuberculosis, and that tuberculosis also causes poverty. Poverty is accompanied by malnutrition, bad housing, and overcrowding, the last tending to produce close personal contact with open cases. In view of the great overcrowding in so many of our great cities we cannot expect any automatic reduction in tuberculosis in the near future. As McGonigle observed, better housing without a rise in real wages may, owing to raised rents, lead to deterioration in nutrition.

The steady rise in the real value of wages seems to have been a major cause of the reduction of tuberculosis mortality, but this rise was checked at the turn of the century and reversed during the 1914–18 war (Hart and Wright, chart 4), and appears to have been reversed in and after the 1939–45 war. Thus the index of real earnings, which was 127 in 1875, had risen to 244 in 1939 and has fluctuated since then. A fall in this index also occurred in the 1914–18 war, reaching 176 in 1913 and falling to 146 in 1916; it rose, however, to 205 in 1920. The economic effects of the recent war have, however, been more serious than in the previous war, and we cannot anticipate any such quick recovery. If this rise in the real value of wages has indeed been the cause of the decline of tuberculosis during the nineteenth century it is urgent that we take stock of the position in which we now stand. At the present time there is a world shortage of foodstuffs accompanied by a high world level of prices of transportable foods. To expect an early resumption of the increase in the real value of wages in this country—though possibly not in the United States—would be tantamount to being blind to the most salient economic feature of the times in which we live. If we translate increased real value of wages into terms of better nutrition and housing, involving greater resistance and less exposure to infection in the home, are these really the sole causes of the reduction of mortality in the past?

*Coefficients of correlation (i, v, and vi are from Pearl, 1940):

- (i) Tuberculosis mortality in *arrondissements* of Paris, 1911–17, and the proportion of the population so poor as to be not assessed to house tax ... +0.977 ± 0.004
- (ii) Total pauperism and phthisis in England and Wales, 1866–1903 (Newsholme) ... +0.89
- (iii) Mortality for respiratory tuberculosis and substandard conditions of housing in 76 county boroughs (Hart and Wright, 1939), 1931, 1931–3:
 - Males 15–24 ... +0.568
 - (iv) Ditto: Females 15–24 ... +0.663
 - (v) Tuberculosis mortality and overcrowding (more than 3 persons per room) in Vienna, 1897 ... +0.892 ± 0.047
 - (vi) Ditto: (more than 2 persons per room) in London, 1908–12 ... +0.774 ± 0.075

Segregation of Infective Cases

Sir Arthur Newsholme (1908, 1923) gave evidence that there was a close parallelism, especially in later years, between the proportion of deaths from phthisis taking place in hospitals and other residential institutions and the general tuberculosis mortality rate. In 1869-70, when the death rate in England and Wales from respiratory tuberculosis was 24.4 per 10,000 population, only 8.3% of the deaths from all causes occurred in public institutions. "In the year 1920, 36.2% of the total male and 26.5% of the total female deaths from phthisis in England and Wales occurred in hospitals, commonly after prolonged, and often repeated, stay of the patients in these hospitals." Newsholme's figures were severely criticized by Alice Lee (1915) on the ground that his measures of segregation were badly chosen. Power (1908) had earlier cast doubts on the validity of Newsholme's conclusions as applied to the nineteenth century.

I have been able to investigate the matter further, so far as it relates to deaths from tuberculosis (mainly phthisis) in the hospitals and institutions of the city of Liverpool during the period 1860 to 1946, by taking samples at five-yearly intervals, as shown in the following table:

Year	Percentage of Deaths from Tuberculosis in Residential Institutions	Mortality from Tuberculosis per 1,000
1860	13.7	4.4
1865	17.2	5.3
1870	14.1	4.1
1875	17.4	3.8
1880	14.4	3.7
1885	21.7	2.9
1890	20.9	2.7
1895	27.6	2.8
1900	37.2	2.5
1905	44.2	2.0
1910	50.5	2.0
1915	35.8	2.0
1920	42.7	1.7
1925	51.0	1.5
1930	51.1	1.4
1935	60.0	1.1
1940	55.1	0.9
1946	57.2	0.9

From these figures we obtain a coefficient of correlation of -0.94 ± 0.017 , which indicates a very high degree of inverse association. It is subject to the criticism that the array of figures is too small for accuracy, but *a priori* it appears probable that the increasing removal of cases of open tuberculosis to hospital has had considerable influence on the reduction of tuberculosis in this country and elsewhere, especially during the present century. One may well think that this factor has played an increasing part in that reduction since the introduction of sanatorium benefit in 1911. The prohibition of indiscriminate expectation may also have helped in reducing infection.

At this point we must face present realities. At the end of 1946 in this country, despite the addition of 2,440 to the number of "tuberculosis beds" provided, there was a waiting-list of 7,025 tuberculous patients (Ministry of Health, 1946). This position arises from a shortage of nurses, especially of sanatorium nurses, and not of beds. In sanatoria the occurrence of a case of tuberculosis among the nursing staff is, in my experience, exceptionally rare. The mortality from tuberculosis among nurses is no higher than that of the general female population of the same ages, but the morbidity would seem to be higher. Any active campaign against tuberculosis, whether preventive or curative, is at present in this country absolutely dependent upon adequate provision of hospital beds. If we investigate anti-tuberculosis programmes in either Scandinavia or the United States there appear to be waiting beds rather than waiting-lists.

The former standard of one sanatorium bed per tuberculosis death per year is certainly out of date. The actual provision in England and Wales is 1.3 beds per death (in Liverpool 1.5), but in Germany it is 2.2 (0.7 in Berlin) and in Canada 2.5; coming to Scandinavia, in Stockholm it is 2.5, in Copenhagen 2.8, and in Oslo 3.0. It is necessary to make the best possible use of available beds, both for the cure of the individual patient and, with emphasis, for the achievement of the best preventive result.

Tuberculosis Among Nurses

I do not think any responsible person in charge of a hospital admitting patients suffering from tuberculosis can be happy about present conditions, under which Mantoux-negative nurses, medical students, and others come into contact with infectious cases. To find that such a person is tuberculin-negative and presents no x-ray evidence of a prior infection seems to require some attempt at least to increase specific resistance, even if complete immunity is out of the question. How far the Bacille Calmette-Guérin (B.C.G.) or the vole bacillus can meet the case I will discuss later. This is a matter of serious importance if we are to continue to nurse infectious, often advanced, cases of tuberculosis away from the home, for it appears highly desirable to increase the proportion of sputum-positive cases so isolated.

One of the factors causing inadequacy of the beds available for the treatment of tuberculosis is the increase in the average length of stay in sanatoria, which now often amounts to twelve months or more. This arises partly from the commendable wish of sanatoria physicians to do the best for their patients and partly from the increasing armamentarium, both medical and surgical, available for treatment. Earlier diagnosis by mass radiography or otherwise has, of course, an opposite effect if the early case can be admitted at once, but often this cannot be done. It is deplorable that such patients have to wait for admission while the most favourable moments for curative treatment are slipping away and while they are possibly becoming sputum-positive to the danger of their families. In 1938 as many as 65% of patients admitted to sanatoria in England and Wales were classified as intermediate or advanced cases.

Alterations in Ages at Death

There is another aspect of the epidemiology of tuberculosis which should be emphasized—namely, the marked differences between the resistance of races that have for long been exposed to tuberculosis and those that have not. Calmette (1923) presented the evidence fully and I have summarized it (Stallybrass, 1931). There can be no question of the reality of these racial differences in resistance to tuberculosis. Cobbett (1925) expanded Calmette's law of tuberculosis into the following: "Peoples are more resistant to the attack of the infectious diseases of their own countries and districts than to that of foreign diseases with which neither they nor their ancestors have been accustomed to come in contact." Among pygmies brought into this country from Africa the disease is rapidly fatal and epidemic in incidence; among Jews who have lived for centuries in towns, often in ghettos, the resistance is high. This clinical difference in the course of the disease is accompanied by a considerable variation in the age at death. Drolet (1930) has published a diagram contrasting the distribution of male tuberculosis deaths per 1,000 among negroes and Jews respectively age by age in 1926-8 in New York City. Both races lived under closely similar housing conditions. This diagram emphasizes two points: (a) the mortality in the first four years of life was about 60% higher among negroes than among Jews; and (b) the peak age at death is about 25 years among negroes and about 45 years among Jews.

difference in modal age at death of about 20 years. Such differences of age at death may be regarded as due to the survival of the fittest following Darwinian selection over a long period.

In Liverpool in the past 90 years there has been a marked reduction in the *deaths* attributed to tuberculosis in the first five years of life. Bearing in mind what was previously said in relation to meningitis and tabes mesenterica, the proportion of infant deaths to the total mortality has markedly fallen. In 1860 it was 15.8% and in 1935 0.8%, but it showed a rise in 1942 to 2.6%, mainly attributable to meningitis. Similar but smaller fluctuations occurred in all ages up to 5 years.

Again in Liverpool, the peak age at death was 20-25 years in 1860-70; that period included the Lancashire cotton famine. It rapidly rose to 30-40 years by 1875, and has so remained with the single exception of 1943—following the air raids—when it fell back to 25-30. There has in fact been a considerable shift towards older ages, even up to 90. In Copenhagen and Stockholm there has been a shift towards younger ages in the *death rates* by ages.

The changes in the Liverpool figures closely simulate Drolet's racial differences. But it is hardly credible that Darwinian selection could have affected these changes in a mere 80 years: social and economic changes seem to provide a more probable explanation.

Differential Sex Mortalities

In 1838, when deaths were first registered, the female tuberculosis death rate was higher than the male. The rates crossed in 1860, and by 1925 the males constituted 60.2% of the total. With the increasing entry of women into industry the *proportion* of female deaths has somewhat increased. In 1901-10 (Newsholme, 1923) there was in urban districts a peak age at 45 for men and at 35 for women, the male rate at those peak ages being 166 per 100,000 in excess of the female rate. In rural areas both sexes had a peak mortality at 25 years and the male excess was slight. The differences in the peak death rates between the sexes had been considerably reduced by 1938-9, being equal to a male excess of 25 per 100,000, but the male peak age had further advanced from 45 to 55 years.

These age and sex differences and changes are closely related to occupational causes. Before the industrial age women worked in the home and were exposed to infection from cases never isolated. Exposure to industrial conditions, especially silica dust, introduced a more chronic form of tuberculosis affecting men; lately the increase in the number of women in industry has increased their exposure to infection, and this was especially true in wartime; at the same time advances in the hygiene of the dangerous trades have tended to reduce the male excess. It would be of interest to know at the next census just what part of the male excess is attributable to the excess tuberculosis mortalities of these dangerous trades. Alcoholism plays a part in the excess male mortalities, but less so than in the past.

Results of Tuberculin-testing

One of the great advances in recent years in our knowledge of the epidemiology of tuberculosis arises from the increasing use of tuberculin for testing that sensitization of individuals which is caused by infection with the tubercle bacillus, whether natural or artificial. The refinements of the Mantoux test with its increasing test dosage of tuberculin have improved the sensitiveness of the method and rendered it superior to the von Pirquet test, which may be negative when the Mantoux test is positive. For this purpose old tuberculin, which contains two proteins of differing

antigenic properties, is commonly used, but in the United States and Denmark P.P.D. (purified protein derivative) is in general use. In either case it is a test of allergic sensitization and not of resistance—much less immunity—but the parallelism between allergy and resistance appears to be sufficient to permit the measurement of the allergy as a rough test of the degree of resistance. It is unfortunate that owing to variations in the strength of the tuberculin used for testing—noticeably in Norway—the results of tuberculin-testing in one country are often not strictly comparable with those in another.

From the extended use of the Mantoux test it is now known that effective infection with *Mycobacterium* is not so widespread, especially in rural populations, as appeared to be the case early in the twentieth century, *pace* Naegeli, Burkhardt, and von Pirquet; later studies of Schuermann (1929) showed pulmonary lesions in only 1.7% of necropsies of those under 30 years of age and 11% of those between the ages of 30 and 45. Many negative tuberculin reactions are found among primitive communities (Topley, 1933), a high proportion of positives among most civilized communities, and a lower percentage of positives in the United States and Scandinavia, especially among those who, from rural location or economic shelter, have probably escaped contact with the bacillus. In Stockholm, states Heaf (1947), at 7-8 years only 8% were reactors and at 13-14 years only 26%. In Stavanger only 22.4% were positive at 10-20 years. In Denmark nation-wide figures show that two-thirds of the population are negative at 14 years; at 20-23 years the proportion is one-third (Holm, 1946). But in Scandinavia, where the use of B.C.G. is rapidly extending, the aim is to raise the proportion of positive reactors artificially. It is considered almost antisocial not to be tuberculin-positive.

The results of x-ray examinations largely confirm the results of the tuberculin tests. Holm states that a great part of those undergoing natural conversion show very prompt x-ray changes. Nevertheless the results of the Prophit Survey (1948) revealed that radiologically visible changes were seldom found when a recent primary lesion had caused a Mantoux-conversion from negative to positive—namely, 7.6% among nurses and 8.5% for London medical students. Malmros and Hedvall (1938) reported 13.9% of the naturally Mantoux-converted showing primary lesions. The Prophit Survey further states that the morbidity following primary infection was proportional to the degree of tuberculin sensitivity noted on natural Mantoux-conversion.

It should be the ultimate objective in tuberculosis control finally to eliminate these *natural* Mantoux-conversions. The Prophit Survey considers that "at the present stage of tuberculosis epidemiology it would be vain to hope to suppress all sources of infection and protect every person from even small infections. Nevertheless, no rational theory of prevention can be based on the theory that stray small infections produce a beneficial immunity. An entirely uncontrolled immunizing process responsible for many thousands of deaths can have no scientific support. Public health measures should therefore be directed to reducing exposure to a minimum. . . . Certainly even if occasional infection cannot at present be prevented much heavy repeated exposure is largely avoidable. The Prophit results have confirmed the importance of repeated exposure as one of the factors in the development of tuberculosis."

Obviously such a view excludes any belief that exposure to natural infection by bovine bacilli can serve any valuable purpose. The figures (Prophit Survey, 1948) relating to the marked decline in tuberculosis mortality in the United States at a time when bovine tuberculosis in cattle has been almost eliminated and pasteurization has become general show that the virtual elimination of infection of

bovine bacilli in man has not served to retard the concomitant fall in respiratory tuberculosis mortality.

But such a view will not be applicable to the use of avirulent tubercle bacilli for artificially increasing resistance to tuberculosis, of which the Bacille Calmette-Guérin is the only strain that has undergone prolonged test; still less would it apply to the vole bacillus, now under trial. Indeed, the Prophit Survey Report says: "Serious consideration should be given to the possibility of undertaking in this country [my italics] investigations into the vaccination of tuberculin-negative young adults, such as hospital workers, entering conditions of particular exposure." The same action is equally indicated in relation to any tuberculin-negative contacts of open cases of tuberculosis.

The Prophit Survey has also thrown light upon the vexed question whether tuberculosis in young adults represents infection, reactivation, or reinfection. The application of Mantoux-testing and radiography enables the first to be largely eliminated so far as the tuberculin-negative are concerned. Formerly much importance was attached to reactivation of old foci, but the proportion of cases of reactivation is possibly smaller than formerly believed. Reliable observations show it to be probable that reactivation of a calcified focus seldom occurs, as the bacilli contained therein are dead, though Blacklock (1947) was able to isolate bovine bacilli from calcified glands. This outlook stresses the importance of the prevention of massive and/or repeated infection.

Control of Contacts

In the prevention of infectious disease the control and immunization of contacts often play the most important part. The greatest attention has been given to the examination and observation of contacts of tuberculosis, but of control in the epidemiological sense there has been little in this country. In France and elsewhere the "œuvre de Grancher" consists in the removal of the infants of tuberculous parents—especially mothers—for an indefinite period. This can be regarded as a counsel of despair: the removal of the patient would appear to be the better plan if no other solution were possible. In Scandinavia the newborn infants of tuberculous parents are vaccinated at birth with B.C.G. and segregated for ten weeks or thereabouts because of the comparatively slow development of immunity in the infant: they are then returned to their homes. Heaf (1947) states that no vaccinated infant in any of the Scandinavian countries has so far succumbed to tuberculous meningitis or miliary tuberculosis. Contrast with this the figures relating to Black Notley Sanatorium, where the tuberculous mother is confined under the most favourable circumstances and is instructed in the prevention of infection of her child. Despite these precautions, of 11 children who were in contact with sputum-positive mothers four contracted tuberculosis and two died—i.e., 36% morbidity and 18% mortality.

There can be no question whatever about the importance of familial contact with tuberculosis. Deeny (1947) showed that in a town in Northern Ireland one-third of all the deaths from tuberculosis occurred in houses where there had been two or more such deaths. Opie and McPhedran's (1926) figures contrasting the rapid development of Mantoux-positive reactions in the child contacts of tuberculous patients in comparison with non-contacts fully demonstrate the importance of infection in the home. Stewart *et al.* (1937) obtained figures of the actual morbidity of contacts in rural areas of Tennessee. They showed that the incidence of subsequent cases in a tuberculous household was 2.06% in the year of onset, 1.33 in the first year following contact with the index case, 1.15 in the second, and lesser figures in the succeeding years.

We may conclude that in the causation of tuberculosis there is an uneasy balance between an increasing resistance—not to infection, but to morbidity and mortality, such resistance being partly racial or genetic, partly nutritional, the latter being closely related to the increase in the real value of wages during the nineteenth century—and massive and/or repeated infection, especially at susceptible ages, as in infancy, and later in adolescence and young adult life. Such massive infection has been greatly reduced throughout the past 80 years, and, speaking generally, increasingly so during the present century. The reduction of exposure in infancy results in an accumulation of susceptible tuberculin-negative adolescents and may cause a relative increase in tuberculosis in young adults because the risks of repeated exposure are much greater in the tuberculin-negative. This susceptibility can be overcome to a considerable extent by the production of artificial resistance. Silicosis, and possibly other adverse industrial conditions, may account for greater and later male mortalities compared with those of females.

Vaccination Against Tuberculosis

B.C.G. is a living avirulent strain of the bovine bacillus which, after 230 successive cultures over a period of 13 years, was employed in 1922 for the vaccination of children born in tuberculous families. It gives a "normal" tuberculin, but has never been recorded as having returned to virulence or produced a general infection in any of the more than 3,000,000 children said to have been vaccinated with it in the past 26 years. Nevertheless the Pasteur Institute has not yet accorded it the status of "virus fixe." All the cultures now used for inoculation are derived from this strain. The Lübeck tragedy was caused by the admixture of virulent bacilli with the B.C.G., and those responsible were convicted of gross carelessness. It is for this reason that B.C.G. should be produced in a laboratory entirely dissociated from other bacteriological work.

Recently by the kindness of Drs. Bøe and Krohn I was enabled to see the Nasjonalforeningens B.C.G. Laboratorium in Bergen, where all the B.C.G. used in Norway is freshly prepared every week; the vaccine should be used within ten days of production, as it is apt to weaken owing to the death of the bacilli. It should therefore be kept in a refrigerator or ice-box. Two strengths are produced, clearly distinguishable by sight, one being obviously turbid and forty times as strong as the other. The stronger one is used only for transcutaneous inoculations. The more dilute emulsion is clear, and is employed for intradermal inoculation. Myren (1948) states that on a certain occasion the stronger emulsion was accidentally used for intradermal inoculation of 66 persons: localized ulceration was the only untoward effect, and the immunity produced appeared to be more durable than ordinarily. However used, it is important, as Holm (1946) points out, that the virulence of the B.C.G. strain should be kept at a proper level, and the bacteriologist at the B.C.G. Laboratory should be kept informed of the results of every inoculation.

The intradermal method has been more generally used, 0.1 ml. of vaccine being injected. It has the advantage that the dosage is more certain; it has the disadvantage that if through poor technique the injection is given subcutaneously a small localized abscess with enlargement of neighbouring lymph glands will ensue. Bacilli from such an abscess are, however, avirulent when cultured. Even so injected the discomfort is minimal and not incommodious.

The transcutaneous or multipuncture method does not suffer from this disadvantage. Birkhaug (1944) gives theoretical grounds for the belief that the skin itself is an antibody-producing organ. Birkhaug's original instrument

released forty needle-points automatically; its use has been given up in Bergen, and five or fewer applications of a holder fitted with eight gramophone needles are substituted. The skin is first cleaned with ether, the thick emulsion vaccine is then spread from a syringe with a needle, and the multipunctures are made. Statistical material is still being collected to evaluate this process. In Bergen, of 10,568 inoculated some 7,894 were controlled after two months; of these, 7,472 (94%) were Mantoux-positive. This result is in no way inferior to those of the intradermal method (personal communication). The objection that Birkhaug's instrument was difficult to sterilize has thus been overcome.

It is a strict rule that all persons must be Mantoux-tested before inoculation, and only those who do not react to 100 tuberculin units (Holm, 1946) should be inoculated. In a few cases men have been inoculated by accident during the allergic state without any untoward result—i.e., there is no negative phase, though an accelerated reaction may occur (Koch's phenomenon). The normal response is that at the end of three weeks raised papules appear at each puncture point. In six weeks a positive Mantoux reaction is usually obtained. In infants this may take ten weeks or even more. For infants 16 punctures, for women and children 24 punctures, and for men 40 punctures are given (Birkhaug, 1944). The use of B.C.G. involves not only the application of the vaccine in the appropriate way but also, if statistical fallacies are to be avoided, subsequent protection from virulent infection until sensitivity is demonstrated.

Results of Vaccination

So much for the methods; what are the results? Space does not permit a full description of even the better-documented experiences relative to but a small fraction of the 7,000,000 persons who have, according to Myers (1948), been vaccinated with B.C.G.; the majority of these have received the vaccine orally. The matter has been discussed by Holm (1946), Aronson and Palmer (1946), Wilson (1947), Heaf (1947), Levine (1947), Malmros (1948), Wallgren (1948a, 1948b), Rosenthal *et al.* (1948), and Aronson (1948). An Empire Conference in London, international conferences in Washington and Paris, and annual conferences in Scandinavia have taken place. The examples below—mainly from Scandinavia, where B.C.G. inoculation is practised on a national scale—are recorded for their apparent success. Given singly, they might not carry conviction to the critical mind; taken collectively, even the hypercritical cannot fail to reach the conclusion that in the varied circumstances the use of B.C.G. has been not merely harmless but endowed with marked protective properties.

1. In the Swedish district of Örebro (Malmros, 1948), in a population of 230,000 there have since 1942 been 22,413 vaccinated with B.C.G.—i.e., 8,040 newborn, 7,836 children over 1 year, and 6,537 adults. During the period 1942–7 only one vaccinated person has been regarded as tuberculous: a nurse, twice vaccinated, developed pleural effusion; there was no definite evidence of tuberculosis. This example does not provide a contemporary control.

2. The island of Bornholm, in Denmark. The comparison here is before and after a period of intensive testing and inoculation since 1945, by which time 10,337 young persons—i.e., 23.3% of the population—were vaccinated (Olsen, 1947; Malmros, 1948). A marked fall in the incidence of tuberculosis resulted at just the ages—namely, 7–35—at which vaccination took place. Notifications fell from 134 in 1935–40 to 82 in 1941–6. The proportion vaccinated is now 27%; 98% of those found tuberculin-negative and offered B.C.G. accepted.

3. Hyge's report on an outbreak in the Aurehoej State School in Denmark (Holm, 1946) has the force of a laboratory experiment, but was excluded by Wilson from his survey of the subject. The school had had Mantoux-testing followed by

voluntary B.C.G. vaccination, the last tuberculin-testing being in December, 1942. The 368 girls were then in three classes: (a) naturally Mantoux-positive, (b) Mantoux-negative who had had B.C.G., and (c) Mantoux-negative who had not received it. Then in January and February, 1943, an influenza-like outbreak occurred, mainly affecting the unvaccinated Mantoux-negative. Suspicion of tuberculosis was aroused by the occurrence of a case of erythema nodosum. It was found that the source of infection was a teacher who had taught in an ill-ventilated classroom while suffering from a supposed "cold," though gastric lavage later revealed tubercle bacilli. Taking the 305 scholars in her class or classroom, the following results were found:

(A) 105 naturally positive. Four cases of genuine pulmonary tuberculosis. Morbidity, 3.8% \pm 1.95.

(B) 106 negative reactors given B.C.G. Two cases of genuine pulmonary tuberculosis. Morbidity, 1.9% \pm 2.6.

(C) 94 negative reactors. December, 1942. Seventy rapidly inverted to positive reactors. Of these 70 inverters 41 showed x-ray changes and 37 had tubercle bacilli; 55 had initial symptoms, 10 had pleurisy (3–11 months after infection), and 1 had peritonitis. Taking those with symptoms and x-ray changes, the morbidity was 43.6% \pm 10.6.

Among the 63 girls not using this classroom there was no illness, and none of the 11 Mantoux-negative reactors in this group became ill. These figures also bear out the belief, held in Scandinavia, that persons who have undergone Mantoux conversion after B.C.G. vaccination, if they *do* develop signs of tuberculosis, usually have a short illness of two or three months and can then leave hospital and have no relapse. Comparisons between A or B on the one hand and C on the other are statistically significant.

4. Heimbeck's figures (per 1,000 observation years) relative to the incidence and mortality of nurses at Oslo (Wallgren, 1948b):

	Morbidity	Mortality
B.C.G.-vaccinated	24.1	2.1
Non-vaccinated	141.2	14.6

5. Rosenthal's experience (Rosenthal *et al.*, 1948) with newborn children born in Chicago during ten years. The mothers were interviewed in the hospital and the children vaccinated before they left the hospital. Contrary to what is done in Scandinavia, no isolation of the child before or after vaccination was carried out.

	Non-Contact		Contact	
	Vaccinated	Control	Vaccinated	Control
Person-years and proved	5,627	6,032	517	284
Tuberculosis rate	1.95	6.46	3.86	17.60
Hospitalized	0.17	2.48	1.98	17.60
Deaths	1	7	0	4
Death rate	0.17	1.16	0	14.0
Deaths from other causes	27	22	3	2

Wilson (1947), after a lengthy review of the present position in regard to B.C.G., concluded that, whilst a presumptive case for the value of B.C.G. has been established the documentary evidence is insufficient to estimate the degree of protection it affords, and he makes certain other criticisms which, in the opinion of Malmros and Wallgren, disregard much of the Scandinavian evidence quoted above.

In September, 1946, a conference on B.C.G. vaccination was held in the offices of the Tuberculosis Control Division of the United States Public Health Service in Washington D.C. The deliberations of the distinguished leaders in tuberculosis from the United States and elsewhere concluded from the studies presented to the conference that B.C.G. vaccination confers increased resistance to tuberculosis for the limited period covered in those studies, and that medical literature reveals no proved cases of progressive disease as a result of B.C.G. vaccination, which can

be done without causing severe local reaction. In these studies B.C.G. converted a large percentage of non-reactors into reactors. The need for revaccination and the time interval between vaccination required further study. It was recommended that a single laboratory be established to produce vaccine for the whole country for use in research programmes prepared by the conference, but that it should not be produced commercially.

In America, with an economic outlook that is favourable in comparison with that of Europe and a falling tuberculosis mortality, an expectant outlook to B.C.G. may be permissible. In Scandinavia the question of the value of B.C.G. is now regarded as a *chose jugée*; it has definitely been adopted there on a national scale. In Norway B.C.G. vaccination is compulsory for certain grades of the population—e.g., the eighth-grade scholars. At the meeting of the Northern Tuberculosis Physicians in Oslo in July last the prevailing opinion was that all children ought to be vaccinated from infancy and that it should be repeated in childhood. It is difficult to become a nurse in Scandinavia without being Mantoux-positive or becoming so.

In this country the position is such that we cannot afford not to have available every resource in the combat against tuberculosis; we cannot possibly be complacent in our attitude towards its prevention. The control of contacts is gravely hampered: I have in mind a family of four children, successively infected from a tuberculous mother and all admitted to hospital, whose illnesses, according to Scandinavian experience, could have been prevented. With the shortage of nurses and of hospital beds at least those Mantoux-negative nurses who wish it should receive the degree of protection that B.C.G. affords. As a minimum programme B.C.G. should be prepared at a separate central laboratory, say in London, as is done in each of the three Scandinavian countries. It does not seem to be necessary to wait another five or ten years, by which time experiments may answer some of the remaining questions concerning B.C.G. vaccination, before it becomes available for more general use under conditions of control such as exist in Scandinavia.

Wells (1947) has vaccinated 121 persons with the vole bacillus, and has not observed anything but localized disease or any enlargement of lymph glands. He states that sensitivity to tuberculin following vaccination with the vole organism is greater and occurs earlier than that following B.C.G. Animal inoculation by itself will secure a fixed level of virulence. Tytler stated that its safety "appears unquestionable, but can hardly be greater than that which practice has proved for B.C.G." (See also Wells, 1946.)

If adequate control of contacts is to be carried out in this country the staff engaged in the purely preventive side of tuberculosis control must be augmented. If from largely being observers they are to be engaged in actively producing immunity their numbers should be at least doubled. In Scandinavia the proportion of tuberculosis officers, measured either by population or by number of cases, is everywhere considerably higher than in Great Britain. When the people are ready to accept vaccination we should be ready to give it. We need a "new look" in tuberculosis control.

Summary

The great decline in tuberculosis mortality that occurred in the later two-thirds of the nineteenth century was caused mainly by improvement in socio-economic factors of which the rise in the real value of wages is the best gauge. This rise in value resulted from the increasing productivity of machines; it facilitated better nutrition and housing, and in the home it involved a lessened exposure of women, and more especially children, to infective cases. For a period bad conditions in industry weighted the conditions against men, silicosis

causing a high mortality in later male life; the male deaths now considerably exceed the female.

In 1911 a factor previously unimportant followed sanatorium benefit, which provided accommodation for the segregation of earlier cases and became increasingly effective. Previously the deaths in Poor Law hospitals took place there largely as a result of destitution. Despite the pause in the rise in the real value of wages—becoming an actual decline in each of the two wars—the tuberculosis death rate continued to fall—markedly so in tuberculous meningitis in infancy and childhood. It is assumed that this was mainly due to the segregation of infective cases, though improved treatment was not without result. Largely owing to the shortage of nurses, this factor was inadequate during and after the last war and can no longer be relied on. In Scotland tuberculosis mortality is increasing, largely among young adults.

Family contacts of known cases form at least one-third of cases of tuberculosis, and the infection of nurses is a serious defect in our present system. Vaccination with B.C.G. (or the vole bacillus) appears to meet present pressing needs, especially as a preventive for the two classes just mentioned. Twenty-five years' experience of B.C.G. has shown it to be harmless; it is universally adopted in Scandinavia, where its use—compulsory in Norway—has led to a marked decline in incidence and mortality among those receiving it. It is recommended by the World Health Organization that it should be provided free; it should be produced centrally and be used, in the first instance, for the prevention of tuberculosis among known contacts of cases.

AN ANALYSIS OF 200 CASES OF ANKYLOSING SPONDYLITIS

BY

N. R. W. SIMPSON, M.B., B.S., D.Phys.Med.

Supernumerary Medical Registrar, Royal National Hospital for
Rheumatic Diseases, Bath

AND

C. J. STEVENSON, M.B., M.R.C.P.

Surgeon Lieutenant, R.N.

In this paper is presented an analysis of 200 cases of ankylosing spondylitis, together with a review of some current ideas on the disease. No attempt is made to cover all its aspects, since the historical and other features have been adequately described by others, notably by Buckley (1945). Data were obtained from the hospital notes of cases admitted to the Royal National Hospital for Rheumatic Diseases, Bath, during the period 1938-48. These do not represent the total number of cases admitted during this period. The records for a number of years were lost as a result of enemy action, and in many other cases the notes were found to be inadequate. Apart from this no selection of cases was made, and the figure was limited to 200 for statistical purposes. All were proved cases of ankylosing spondylitis from both a clinical and a radiological standpoint.

Results of Investigation

Sex Incidence.—There were 158 (79%) males and 42 (21%) females. This percentage of women is higher than has been recorded by other workers, with the exception of Swaim (1939), Gilbert Scott (1942), and Fletcher (1944).

Age of Onset.—The incidence is shown in Table I. In no case did the onset occur before the age of 10 years and in only three cases was it before 15. The results are in conformity with those found by Buckley (1935) and other observers, except that a rather larger number of cases occurred between the ages of 15 and 20.

TABLE I.—Age of Onset

Age	No. of Cases	Percentage
10-20 years	42	21
20-30 "	80	40
30-40 "	45	22.5
40-50 "	21	10.5
50-60 "	11	5.5

In one case the age of onset was not recorded.

Initial Diagnosis.—Only 102 (51%) of the cases were admitted to this hospital with a correct diagnosis already made. This lends further weight to the suggestion of Gilbert Scott (1942) that x-ray examination of the sacro-iliac joints should be a routine investigation in all cases of persistent low-back pain.

Associated Factors

Sepsis.—There was a history or evidence of focal sepsis in 22 cases. This did not include dental caries without abscess formation. The sites of focal sepsis were catholic in distribution, and only three were confined to the pelvis. This is of interest in view of the suggestion made by Buckley (1945) of the importance of infection from the pelvis in this disease.

Trauma.—Thirty (15%) patients gave a history of trauma, which they associated in some way with the onset of symptoms. This trauma varied in severity and anatomical distribution, and the assessment of its significance has proved impossible.

Exposure to Excessive Fatigue and Shock.—Thirteen (6.5%) cases gave a history of this, but taking into consideration the war years and occupational hazards this was not regarded as extraordinary or significant.

Childbirth.—Five of the 42 women patients stated that their symptoms dated from the birth of a child. Others were unaffected by childbirth. A follow-up of this finding might be profitable in view of the pelvic trauma and the physiological changes in the sacro-iliac joints at parturition.

Family History.—In only two cases was there a family history of ankylosing spondylitis. In three cases there was a family history of gout, and 31 revealed a family history of acute or chronic rheumatism.

Past History.—There appeared to be no significant relation between any previous illness and the condition. In only 18 cases was there a history of fibrositis or other rheumatic condition, and in certain of these cases the nature of the complaint seemed vague and of no statistical value.

Occupations.—These were classified as: (1) occupations involving physical effort—heavy 41 (20.5%), medium 92 (46%), or light 32 (16%), and (2) sedentary occupations 30 (15%). In five cases it was not recorded. In this series occupation appears to have little relation to the aetiology of the disease.

Iritis.—In 12 (6%) cases iritis was found. Campbell (1947) and Fritz (1937) report a higher incidence.

Subcutaneous Nodules.—In no case, in spite of a diligent search, were nodules found. In view of their incidence in rheumatoid arthritis this is significant.

Chest Expansion.—In five patients this was more than 3 in. (7.5 cm.), in 20 it was between 2 and 3 in. (5 and 7.5 cm.), in 22 between 1½ and 2 in. (3.75 and 5 cm.), in 27 between 1 and 1½ in. (2.5 and 3.75 cm.), and in 52 less than 1 in. In 74 cases it was not recorded. The vital capacity was estimated in 15 cases with the following results: 5,000-4,000 ml., 1; 4,000-3,000 ml., 2; 3,000-2,000 ml., 5; and below 2,000 ml., 7. In the majority of cases great improvement was noted before discharge. This supports the value of institutional treatment with adequate physiotherapy, especially breathing and postural exercises, and the use of a plaster bed in the acute stage.

Loss of Weight.—Initially 108 (54%) patients were found to have lost weight, in 26 (13%) there was no loss, and in 66 (33%) this point was not recorded.

Type of Onset.—In 62 (31%) cases the onset was acute and of such severity that the patient was confined to bed; in 114 (57%) it was insidious, usually over years; and in 24 (12%) the type of onset was not recorded.

Initial Symptoms.—These consist of pain and/or stiffness: the site in order of frequency is shown in Table II.

TABLE II.—Initial Symptoms

Site	No. of Cases	Percentage
Low back	75	37.5
Low back and other sites ..	33	16.5
Hips	23	11.5
Low back and hips	20	10.0
Knees	15	7.5
Sciatic pain	12	6.0
Feet and ankles	6	3.0
Cervical spine	5	2.5
Dorsal and cervical spine ..	4	2.0
Dorsal spine	3	1.5
Hips and knees	1	0.5
Cervical and knees	1	0.5
Shoulders	1	0.5
Unrecorded	1	0.5

Corrected Suspension Stability and Sedimentation Rate.—Abnormal readings at some stage were found in 182 (91%) The grossly abnormal readings were seen when the disease process appeared to be most extensive and most active

It is our impression that nearly all cases of ankylosing spondylitis will show an abnormal corrected suspension stability and erythrocyte sedimentation rate during the active phase of the disease. The figures obtained in many cases were very abnormal, even more so than those we usually see in rheumatoid arthritis.

Haematocrit.—In 154 (77%) there was a low haematocrit reading. This is in conformity with the view that cases of ankylosing spondylitis show a secondary anaemia during the active phase. Red cell counts supported this in the great majority of cases. White cell counts showed little gross abnormality, but Arneth counts revealed a shift to the left in 20 out of 24 recorded cases.

Blood Proteins.—Plasma protein estimations in five cases showed little gross abnormality except an occasional high total protein figure and a consistently high value for fibrinogen. Albumin, globulin, and the A./G. ratio were always within normal limits. This is in conformity with a larger series done recently in this centre. These results are in contradistinction to the findings in rheumatoid arthritis, in which abnormal plasma proteins were found in approximately 50% of cases (Simpson and Hall Brooks, 1948).

Plasma Uric Acid and Blood Uric Acid.—These were estimated in 178 (89%) cases and were normal in all except four cases in which the figure was slightly raised, but the plasma uric acid was never above 7.5 mg. per 100 ml.

Wassermann and Kahn Tests.—At least one of these tests was done in all cases, and without exception the result was negative.

Alkaline and Acid Phosphatase.—In only 27 cases were these results recorded and in only four were the readings raised—in two the acid phosphatase was 7 and 6.6 units, and in the other two the alkaline phosphatase readings were 15 and 11.5 units (King method). This is in conformity with the opinions expressed by Desmarais (1948), and is of interest in view of the findings of McWhirter (1945) and others.

Muscle Biopsies.—This investigation was carried out in 18 cases and none showed the changes found in rheumatoid arthritis. Muscle biopsies performed in this hospital on cases other than in this series also showed no abnormality as seen in rheumatoid arthritis (Desmarais, Gibson, and Kersley, 1948).

Aurotherapy.—Thirty-six patients had been given courses of gold—20 showed no subjective or objective improvement, in nine there was some subjective improvement, and in seven the results were not recorded.

X-ray Therapy.—It is our custom to give a series of six applications, each of 225 r, in a period of two to three weeks to each affected part. Of 99 cases receiving such treatment 68 showed improvement. This consisted chiefly in relief of pain and stiffness. We find it difficult to say whether the disease process was ever arrested, but we are at present engaged on a follow-up of patients from this point of view and hope to publish the results in the near future. Fourteen cases were not improved from the point of view of pain or any other symptoms. In 17 cases the result was not recorded. We consider that the result of deep x-ray therapy, especially the relief of pain, justifies this form of treatment in all cases, and that it should be initiated as soon as possible.

Radiographic Findings

For the sake of convenience we divided our results into four types (Table III). In type 1 bony ankylosis had occurred, in type 2 gross changes but no ankylosis were found, type 3 showed osteoporosis or other minimal changes alone, and in type 4 there was no abnormality.

TABLE III.—Analysis of X-ray Findings

	Total	Type 1	Type 2	Type 3	Type 4
Sacro-iliac joints ..	173	155	18	0	0
Lumbar ..	167	138	7	16	6
Dorsal ..	120	75	10	23	12
Cervical ..	88	65	7	4	12
Hips ..	141	28	46	27	40
Shoulders ..	12	0	2	9	1
Knees ..	14	4	4	5	1
Hands ..	32	0	2	11	19
Feet ..	4	0	0	3	1
Ankles ..	1	0	0	1	0
Symphysis pubis and ischium ..	21 showed "wooliness"				

Discussion

Certain workers, notably in the U.S.A., favour the concept that the disease is a variant of rheumatoid arthritis (Boland and Present, 1945; Lennon and Chalmers, 1948). From a study of this series of cases we regard it as a separate entity. Our reasons for so doing are: (1) in no case has a subcutaneous rheumatic nodule been found; (2) muscle biopsies have never shown the changes associated with rheumatoid arthritis; (3) plasma protein values are not similar to those seen in rheumatoid arthritis; (4) the high incidence in males, the beneficial effect of deep x-ray therapy, and the ineffectiveness of chrysotherapy are unlike the findings in rheumatoid arthritis; (5) the x-ray appearances as seen in the spine, hands, and other joints are unlike those normally seen in typical rheumatoid arthritis; and (6) permanent deformities typical of rheumatoid arthritis were not present in the hands or feet in any case in this series.

In 75 (37.5%) cases the initial symptom was pain and/or stiffness in the low back. In 53 (26.5%) other cases symptoms were referable to the low back and other sites concurrently. Initial peripheral joint involvement (elbows, wrists, hands, knees, ankles, feet) accounted for 21 (10.5%) cases. In 12 (6%) peripheral joint involvement occurred initially in combination with involvement of other joints. This is of interest in view of the findings of peripheral joint involvement by Boland (1946) and Boland and Shebesta (1946), whose figures vary between 18 and 30%.

An analysis of our x-ray results shows agreement with the views expressed by other authorities, especially Steven (1947). It will be noted that bony ankylosis had occurred in 155 of the 173 cases in which x-ray films of the sacro-iliac joints were available. This shows that in the majority of our cases we were dealing with the advanced stage of the disease, but earlier x-ray films were available of a certain number of these cases before ankylosis had occurred. We are agreed that the earliest changes seen radiologically are osteoporosis of the affected bones (sacrum and ilium) and a subarticular zone of osteosclerosis. We are not clear which of these changes is primary or whether they occur simultaneously.

The next most frequent site to be involved is the lumbar spine. There was no case in this series in which we found involvement of the lumbar spine without involvement of the sacro-iliac joints. In one case, in the early stages, unilateral involvement of the sacro-iliac joints was seen; later films revealed bilateral changes. We are impressed with the frequency with which the articulation between D12 and L1 is involved. This probably is secondary to the considerable stress at this joint.

The radiological changes at other sites generally corresponded with the severity of the disease and the location of the symptoms. In only two of the 32 cases in which the hands were x-rayed was there evidence of extensive changes. These consisted of translucent areas in the shafts of the metacarpals and phalanges (unlike the erosions seen

in rheumatoid arthritis), together with a generalized osteoporosis. In 11 cases osteoporosis alone was seen, and in 19 nothing abnormal was detected. The osteoporotic and other changes were associated with a severe and widespread phase of the disease, but in no case did we see changes characteristic of rheumatoid arthritis.

The biochemical and haematological data are self-explanatory and agree with the findings of other workers.

Summary

Two hundred cases of ankylosing spondylitis are reviewed. Sex incidence, age of onset, associated factors, accuracy of original diagnosis, occupation, and family and past histories are enumerated.

The original symptoms and type of onset are described, as are the biochemical and haematological findings.

The nature of the disease process is discussed, especially in its relation to rheumatoid arthritis, and we conclude that it is a separate entity.

The analysis of the x-ray findings is discussed.

We would like to thank Dr. H. J. Gibson, Dr. G. D. Kersley, and Mr. J. Bastow for their help and encouragement in preparing this paper, and Dr. Steven for his help with the radiological details.

SIGNIFICANCE OF CLUBBING OF THE FINGERS

BY

W. P. U. JACKSON, M.D., M.R.C.P., D.C.H.
 Assistant Physician, Selly Oak Hospital, Birmingham

Perhaps we are rather too apt to regard clubbed fingers as dire omens. Lovibond (1938) stated: "The discovery of clubbed fingers is condemning to the patient . . . long known to be associated with grave disease." Familial clubbing, however, without clinical significance, in which the inheritance is of Mendelian dominant type, is well recognized (Horsfall, 1936; Seaton, 1938; Mendlowitz, 1942; Davis, 1946), although Witherspoon (1936) found only 14 families reported in the literature. Mendlowitz gave an exhaustive list of conditions associated with clubbing, at the same time pertinently remarking that "mere coincidence in isolated cases is not sufficient evidence of a causal relationship." Among associated conditions of less serious import he included simple deformities of the chest wall and uncomplicated emphysema and bronchitis, although these associations were rare. He even quoted "idiopathic," apparently non-familial, cases in quite healthy people (Campbell *et al.*, 1938; Becher, 1941).

In the course of a few months several people were seen whose fingers and toes were clubbed but who suffered from no ominous disease. Brief examples follow.

Cases without Ominous Disease

Case 1: Chest Deformity (? Congenital).—A soldier aged 33 was admitted to hospital with tonsillitis. His fingers and toes were markedly clubbed. He was sure that they had always been that shape, but knew of no similar ones in the family. He had no history, symptoms, or signs of lung or heart disease, and all investigations were negative. He also had a deformity of the chest wall on the right side involving ribs 6, 7, and 8, which were concave in the anterior axillary line, producing a considerable hollow. This had also been present all his life.

Case 2: Familial.—A sergeant-major was admitted to hospital for investigation of his headache (migrainous). He had gross clubbing of the fingers and toes, and also an apparently congenital varus deformity of the fifth toes. There was no history referable to chest complaints; full investigations were negative, and had been so previously at another hospital. He knew he had had clubbing for at least 20 years, and said that his son, aged 2, had had exactly similarly shaped fingers and toes since birth. Another interesting fact was that three of his sisters were said to have died from pneumonia. There was no tuberculous disease in the family.

Case 3: Familial.—A man aged 41 was admitted for investigation of his dyspepsia. He had no history of chest disease, but his fingers and toes were clubbed. His two children, aged 5 and 2, were normal in this respect, but his mother's digits were also clubbed. He had no brothers or sisters.

Case 4: No Apparent Associated Condition.—A middle-aged man came to the out-patient department with a fractured finger. All his fingers were clubbed and, he thought, had always been so shaped. He had no history or symptoms of medical disease, investigations were negative, no congenital abnormalities were discovered, and there was no family history of clubbing.

Case 5: Emphysema.—A man aged 62 was admitted for investigation of his sciatic pain. For many years he had had some winter cough and shortness of breath. He had clubbed fingers and toes and fairly marked emphysema, but no disease of the chest beyond this could be discovered after full investigation.

Case 6: ? No Associated Condition.—An airman aged 21 was admitted with mild febrile laryngitis and bronchitis. He rapidly recovered, but continued to complain of a cough, which was quite dry, some shortness of breath, and vague chest pains. There were no abnormal signs whatsoever except for clubbing of the fingers, which had been present at the beginning of his mild illness. Full investigations were negative.

Case 7: Chronic Bronchitis.—An airman aged 36 complained of a chronic cough all the year round since he was 10 when he had had pneumonia. He had some white sputum in the mornings and some dyspnoea on exertion. Examination revealed nothing at all beyond gross clubbing of the fingers and toes. Bronchography was normal.

Case 8: Past Chest Disease.—An airman aged 30 gave a history of pneumonia at the right base at the age of 5. When 17 he had been in a sanatorium for six months with tuberculosis of the right lung, which had been pronounced cured, and the patient had remained tubercle-free since. He had had rather doubtful attacks of "bronchopneumonia" (? site) since this and frequent bronchitis with greenish sputum but no blood. On examination he was undersized—5 ft. 6 in. (1.68 m.) in height—and looked much younger than his 30 years. He had clubbed fingers and some flattening of the right suprascapular region only. X-ray films of the chest and bronchography were perfectly normal.

Comment.—Certain points arise. In Case 1 the clubbing might be the result of the congenital chest deformity; but might it not be an associated congenital abnormality?—especially as Case 2 also showed a congenital skeletal deformity which could only be an associated condition. Could there be any relation between the familial clubbing in Case 2 and the sisters' pneumonia? Case 8 was interesting in that the clubbing was presumably related to past chest disease, had not subsided with healing of the lungs, and was associated with infantilism. Case 6 had been

diagnosed as having bronchiectasis, had been down-graded to 3, and his discharge from the R.A.F. had been recommended at another hospital. We found no evidence in support of this diagnosis and did not act on the recommendation. Case 7 was also incorrectly labelled "bronchiectasis." This seems to be the important point arising from these cases—namely, that a chronic cough and clubbed fingers are not sufficient for a diagnosis of bronchiectasis, with its consequent gloomy prognosis, although it is apparently not rare for this combination to be so evaluated without exclusive investigation having been made.

Cases with Unusual Features

Other cases showing clubbing that were seen in the same period seem worthy of note because of unusual features

Case 9: Rheumatic Heart Disease.—A boy aged 8 was admitted with chorea. Two years previously he had had the same malady. There were perfectly typical physical signs of well-established aortic incompetence and mitral stenosis, but there was no suggestion of congenital heart disease in his history or on physical or radiological examination. His fingers and toes were markedly clubbed. There were no signs of heart failure. His parents had not noticed the unusual shape of his fingers until it was pointed out to them. There was no family history of clubbing.

Case 10: Cardiac Failure.—A man aged 53 was admitted to hospital in a state of congestive heart failure, with bilateral hydrothorax. His history of shortness of breath went back six months. There was no history of cough or of previous chest trouble. He showed early but definite clubbing of the fingers. The cause of the heart failure was doubtful; there was no evidence of valvular disease and the blood pressure was not raised, although the apex thrust was beyond the nipple line. After aspiration of the chest and routine treatment an x-ray film of the lungs was entirely clear except for rather heavy root markings.

Comment.—Chronic congestive heart failure with mitral stenosis is an established cause of clubbing and was described by Thorburn in 1893, but clubbing in other types of failure without congenital lesions, and clubbing associated with rheumatic heart disease without failure, must be rare. Could the hydrothoraces in Case 10 be the salient factor in its development?

Case 11: Primary Lung Cancer.—A sailor aged 46 was admitted with the symptoms and signs of a space-occupying lesion in the left post-Rolandic area of the brain. Otherwise he had no complaints or physical signs except for clubbing of his fingers. An x-ray film of the chest showed a small faint round shadow in about the centre of the left lower lobe. At necropsy this shadow was found to have been caused by a primary carcinoma no bigger than 1 in. (2.5 cm.) in diameter. There were secondaries in the brain, but the lungs were otherwise normal. That so small a lesion should have produced clubbing is yet a further argument against the operation of a mechanical pulmonary factor in the production of this condition. Similar cases have been previously reported (Mendlowitz, 1942).

Case 12: Infective Hepatitis.—A boy aged 8 was admitted with typical mild infective hepatitis. His liver was palpable and he was moderately jaundiced. His fingers were normal on admission but showed marked clubbing after a fortnight. Unfortunately I do not know what happened to him later. Although hepatitis is a recognized uncommon cause of clubbing, such rapidity of development is rare in conditions other than empyema and lung abscess.

Summary

Some cases of clubbed fingers with certain unusual features are briefly reported. It is particularly stressed that clubbing by itself may be of little significance, and when combined with a chronic cough is not sufficient to justify a diagnosis of bronchiectasis, although measures should certainly be taken to exclude this possibility.

It is realized that only one of these cases came to necropsy for final confirmation; but, clinically and from a practical standpoint, there was no doubt about the correctness of the interpretations.

A CASE OF CONGENITAL TUBERCULOSIS

BY

J. W. JORDAN, M.D., M.R.C.P.

Assistant Medical Officer, Archway Group of Hospitals

AND

H. SPENCER, M.D., F.R.C.S.

Assistant Pathologist, Central Histological Laboratory Archway Hospital

In previous reviews of the literature of congenital tuberculosis (Beitzke, 1935; Hughesdon, 1946), only eight cases of which appear to have been reported in this country up to 1946, the difficulty of proving the congenital origin of the disease has always been stressed. This difficulty is usually all the greater because important evidence is often lost through the destruction of the placenta at the time of birth. Proof of many of the cases reported has therefore had to rest on circumstantial evidence and on the exclusion of possible extruterine causes of infection. Dorothy Price (1948) has laid down three requirements for establishment of the congenital origin of the tuberculous infection; they are, (1) proof of tuberculous infection in the mother, (2) demonstration of tuberculous infection in the child, and (3) exclusion of the possibility of infection of the child after birth.

It has been customary to group cases of congenital tuberculosis into two main types—those in which infection reaches the foetus via the umbilical vein, and those in which it arises from infected amniotic fluid. This second mode of infection usually occurs through ingestion of such fluid by the foetus, in which case the primary seat of the disease is in the intestinal tract, resulting in enlargement of the mesenteric glands and later of the glands of the porta hepatis. It has also been maintained that infection from amniotic fluid may be caused by aspiration of the fluid into the air passages. The view that the foetal lung is normally capable of respiratory movement, so that amniotic fluid may enter the alveoli, as maintained by Snyder and Rosenfeld (1937), has been contested by Whitehead *et al.* (1942), who showed that in guinea-pigs this did not occur. They observed that, so long as anoxia conditions were avoided, thorotrast injected into the amniotic fluid was not aspirated into the lungs. Thus the view that congenital tuberculosis may have its origin in aspiration of infected fluid, except possibly during parturition, must at least be open to doubt.

Hughesdon (1946), in a review of 35 cases described between 1935 and 1945, states that the average duration of extrauterine life was 36.5 days in those cases in which it was stated. A few of the patients lived for a considerably longer period. In every case the tuberculous lesions found at necropsy were commensurate with an infection of much longer standing than the duration of extrauterine life.

Almost all such cases showed at necropsy a miliary blood-stream spread of the disease irrespective of the mode of origin of the infection.

In their clinical course most of the cases of the ingestion type of infection have shown a certain similarity; at birth the child appeared to be normal and for a time gained weight, but later loss of weight, diarrhoea, and sometimes jaundice appeared, and death rapidly ensued in a few days. The case reported below followed such a course. Both the infant and the mother died within a short time of each other, and in both cases a post-mortem examination was carried out.

Case Record

A woman aged 31 was discovered on routine antenatal examination in October, 1947, to be suffering from pulmonary tuberculosis. She was admitted to Grove Park Hospital on Oct. 25, and subsequently was transferred to Lewisham Hospital, where there is a special unit for tuberculous patients in the obstetric department. She was delivered on May 2, 1948. Labour was spontaneous and lasted 15½ hours, but was accompanied by a severe post-partum haemorrhage of about 3 pints (1.7 litres). The placenta was expressed but was incomplete, the small remaining portion being removed from the uterus four hours after completion of the second stage. No other abnormality of the placenta was observed. The infant was immediately isolated from the mother, who on the day following delivery developed a pyrexia ranging between 99.6 and 102° F. (37.55 and 38.9° C.). The mother died about three weeks later.

The infant was a full-term male child, apparently quite healthy. Its weight at birth was 8 lb. 14 oz. (4 kg.). Progress was satisfactory, and on the seventeenth day he was transferred to a nursery, routine medical examination at this time revealing no abnormality. On the twenty-second day it was observed that he was taking his feeds poorly and was lethargic, and the temperature had risen to 101.6° F. (38.7° C.). The abdomen was distended and there was a mild degree of jaundice. On the twenty-sixth day he was transferred to hospital, where on examination the temperature was found to be slightly raised, the abdomen distended, and the spleen greatly enlarged, extending downwards into the left iliac fossa. The liver was also somewhat enlarged, and the sclerae and skin were slightly jaundiced. The infant was not dehydrated. A blood count at the time showed red cells 3,300,000 per c.mm.; haemoglobin, 64% (Haldane), white cells, 11,100 per c.mm. (56% polymorphonuclear leucocytes, 36% lymphocytes, and 8% monocytes); there were also a small number of primitive red cells. The blood Wassermann reaction was negative.

While in hospital the difficulty of getting the child to take his feeds persisted, the jaundice became deeper, and the stools were relaxed and offensive. Four days after admission—that is, thirty days after birth—he died.

All the staff who came into contact with the infant, both in the hospital in which he was born and in the nursery to which he was subsequently removed, were later examined radiologically for tuberculosis, with negative results.

Pathological Reports

Post-mortem Examination of the Mother.—*Generally disseminated tuberculosis, tuberculous peritonitis and salpingitis; chronic pulmonary tuberculosis*—Cavities (up to 2 cm. in diameter) with adjacent fibrocaseous nodules in upper lobes of both lungs. Numerous miliary granulomatous tubercles in lungs. Dense fibrous adhesions at left apex, obliterating left pleural cavity. No macroscopic tuberculous infection in hilar lymphatic glands. Bilateral chronic fibrocaseous tuberculous salpingitis; caseous material in lumina of fibrotic Fallopian tubes. Subinvolution of uterus, compatible in size with a four-months pregnancy; slight purulent endometritis with fibrin and blood clot still attached to the shrunken placental site. Slightly serous caseogranulomatous tuberculous peritonitis, with adhesions between the loops of intestine. Granulomatous tubercles in posterior abdominal lymphatic glands. Miliary granulomatous tubercles in spleen, kidneys, and liver. Slight subendocardial fatty change in ventricular walls of heart. Slight congestion of surface of brain. No abnormalities in

stomach and intestines and endocrine system. Physiological activity of breasts. A slightly wasted, well-developed woman.

The chief findings included chronic bilateral pulmonary tuberculosis and cavitation with superadded terminal miliary tuberculosis. In addition there was a chronic bilateral tuberculous salpingitis, which had almost certainly been present during at least the latter few months of the last pregnancy, and a more recent generalized hyperplastic tuberculous peritonitis.

Post-mortem Examination of the Infant (Dr. A. B. Bratton).—*Generally disseminated tuberculosis; caseous tuberculosis of lymphatic glands in hilum of liver*:—A wasted, well-developed infant showing slight jaundice of sclerae. Mass (2.5 cm. in diameter) of caseous lymphatic glands in hilum of liver; smaller caseous, coeliac, para-aortic, and lumbar glands; caseous glands (up to 1.5 by 0.7 cm.) at bifurcation of trachea and in hilum of both lungs. Very numerous caseous nodules varying from pin's head to 1.6 cm. diameter in enlarged spleen (7.5 by 5 by 4.5 cm.) (see Fig.). Caseous tubercles up to 0.2 cm. diameter

Photograph of the child's spleen, showing the large caseous area and enlarged lymphatic glands in the hilum.

and submiliary granulomatous tubercles scattered through liver. A few submiliary granulomatous tubercles in and cloudy swelling of kidney. Two caseous foci (largest 0.4 cm. in diameter) in lower lobe of right lung and one in lower lobe of left; a few miliary granulomatous tubercles and an occasional area of caseating bronchopneumonia in rest of lungs. Cloudy swelling of myocardium. Oedema of pancreas. No abnormality in adrenals, stomach, intestines, bladder, prostate, or testes. Oedema and congestion of brain.

The lesions in the spleen and lung contained masses of acid-fast and alcohol-fast bacilli in Ziehl-Neelsen stained sections. Many of the lesions were advanced and appeared to be at least a month old. No primary focus was found in any of the usual sites. The most severe lesions were in the glands in the hilum of the liver; these had caused jaundice by pressure on the bile ducts.

Comment

We consider this case to be one of congenital tuberculosis for the following reasons: (1) The clinical course of the child's extrauterine life was similar to that of other cases recorded. (2) Post-mortem examination showed tuberculous lesions commensurate in size and distribution with intrauterine infection. Whether these were due to blood-borne infection through the umbilical vein or to ingestion of infected amniotic fluid is uncertain, but infection was more likely to have been through the former route, as the glands in the porta hepatis were those most enlarged. (3) Post-mortem examination of the mother subsequently revealed active genital tuberculous lesions, which were certainly present during the latter part of the intrauterine life of the child. (4) Immediate removal of the child from contact with the mother and failure to find any subsequent source of tuberculous infection among members of the

staff attending the child make it almost certain that the mother was the source of infection.

We wish to thank Dr. C. D. Coyle, medical superintendent, Archway Group of Hospitals; Mr. Alistair Gunn, consulting obstetrician, and Dr. Simmons, senior physician, Lewisham Hospital; and Dr. A. B. Bratton, senior pathologist, Archway Group Histological Laboratory, for the use of their records of the cases. We also wish to thank Dr. S. M. Tracey, assistant M.O.H. of St. Pancras, for x-raying the staff of the nursery, and Dr. A. L. Jacobs, senior physician, Archway Group of Hospitals, for his helpful criticism.

THE MEAT RATION AND BLOOD LEVELS INVESTIGATION OF INDIAN SOLDIERS IN PERSIA AND IRAQ, 1944

BY

GEOFFREY F. TAYLOR, M.A., M.B., B.Ch.
Colonel, I.M.S. Ret.

P. N. CHHUTTANI, M.D. Punjab

AND

SHIV KUMAR, M.B., B.S. Punjab, M.Sc.

The striking contrast between the vegetarians and the meat-eaters of the Indian soldier population at Shaiba Iraq in the incidence, severity, and type of anaemia suffered (Taylor and Chhuttani, 1945) promoted an investigation into the blood levels of the apparently healthy men on full duty.

The garrison had about 17,000 meat-eaters and 1,188 vegetarians. Two units (S and B), each with a strength of over 500 men and well over 50 vegetarians, were chosen because among the vegetarians in unit S the incidence of nutritional macrocytic anaemia was high whereas unit B was the only major unit without a single case of anaemia for at least a year previous to the time of the investigation. The material was not selected, any two meat-eating and vegetarian soldiers being sent each day by unit authorities from among those who were doing full duties.

Blood was taken in oxalated flasks from the vein first thing in the morning, before breakfast, and sternal puncture was performed at the same time. In addition to a full clinical examination, including search for signs of malnutrition, stools were examined for helminthic and protozoal infection in all cases. The haematological investigations were carried out in the field laboratory attached to the hospital by the workers who had done the anaemia cases; they were not aware of the clinical features or the dietetic habits. Cytological nomenclature and the haematological technique of the earlier investigation were adhered to (after Napier and Das Gupta, 1942). The erythrocyte sedimentation rate was estimated by Wintrobe's tubes before spinning them for corpuscular volume estimation.

Forty meat-eaters and forty-two vegetarians from unit S were examined during August–November, 1944. The inquiry had to be suspended when twelve unit B men from each batch had been examined; the data yielded by this unit were thus referred to for one significant feature only. Men from unit S had been in Shaiba for one and a half years and the majority were from United Provinces of India.

The meat-eaters and the vegetarians were served from the same kitchens. The vegetarians had never taken meat

or eggs in their whole life. We often visited unit S camp to acquaint ourselves with the living, eating, and working conditions of the two dietetic groups; these were found to be alike in all respects except that the vegetarians on account of their social customs did not consume the weekly ration of 20 oz. (570 g.) of fresh mutton. The unit was carrying out pioneer duties of a heavy nature entailing a 44-hour week.

The daily rations were: 18 oz. (510 g.) of atta (wheat flour) or rice, 2½ oz. (70 g.) of dal (pulses), 3¼ oz. (92 g.) of ghee (clarified butter or vegetable oil), ¾ oz. (19 g.) of condiments, 2 oz. (57 g.) of onions, 2 oz. of potatoes, 4 oz. (114 g.) of fresh vegetables, 2 oz. of unsweetened tinned milk, and 6 oz. (170 g.) of fresh mutton with bone for five days in the week. Leafy vegetables were issued for only a few months of the year. In lieu of fresh meat vegetarians were allowed 4½ oz. (128 g.) of tinned milk three days a week and ¼ oz. (21 g.) of ghee and 3 oz. (85 g.) of atta or rice for two days a week, but none of the vegetarians of unit S had received these. No one had supplemented his rations from canteen or elsewhere. The meat ration of 6 oz. of fresh mutton with bone for five days a week amounted to 4 oz. without bone; this was checked in local carcasses. The total daily intake was over 3,000 calories and over 80 g. of vegetable protein.

Haematological and Clinical Features

Peripheral Blood

The various averages obtained are shown in Table I. The average means of red cells and haemoglobin were significantly higher among meat-eaters than among vegetarians (5,550,000 and 4,670,000; 15.44 and 14.32 g.).

TABLE I.—Haematological Averages of Meat-eaters and Vegetarians

	Meat-eaters (40)				Vegetarians (42)			
	Range	Mean	S.D.		Range	Mean	S.D.	
Red cells (millions/ c.mm.)	4.46–6.85	5.55	0.58		1.9–6.6	4.67	0.9	
Haemoglobin (g./100 ml.)	11.1–19.6	15.44	1.4		7–17	14.32	1.71	
M.C.H.C. %	21.7–35.5	28.25	2.32		23.6–33.7	28.54	1.71	
M.C.V. (c.µ)	80–114	96.33	8		80–153	109.48	13.4	
E.S.R. (Wintrobe)	1–20	4.43	4.24		1–37	10.64	9.15	
Total W.B.C.	3,000–9,000	6,022	1,843		3,000–9,000	5,600	1,524	
Neutrophils %	3–72	60.4	10.38		3–74	58.25	9.38	
Lymphocytes %	20–82	31.7	10.52		15–55	35.68	10.34	
Mononuclear %	1–8	4.64	1.76		1–9	3.86	2.35	
Eosinophils %	0–8	2.64	1.76		0–12	2.04	2.59	
Basophils %	0–4	0.54	0.91		0–1	0.25	0.44	

* For the leucocyte count only 33 meat-eaters and 28 vegetarians were observed.

The range and the distribution around the average mean (the standard deviation), especially of red cell counts, were quite abnormal among vegetarians. Whereas there was only one instance among meat-eaters of a red cell count below 4,500,000, there were seventeen among vegetarians. Eight of the latter had red cell counts of 4,000,000 and below, two showing marked anaemia with red counts of under 2 and under 3 millions per c.mm.; all the eight had an M.C.V. above 110 c.µ. Though the average haemoglobin value for meat-eaters was significantly higher than for vegetarians, the difference was not so marked as with the red cell counts. (The explanation of this selective effect on red cell levels in vegetarians lies in the macrocytic type of blood picture exhibited. In haemopoietic-principle (or principles) deficiency anaemia the red cells suffer more than haemoglobin, but in iron-deficiency anaemia it is the haemoglobin which drops relatively more than red cells.) There were five vegetarians and one meat-eater with a haemoglobin value of less than 13 g. Average mean corpuscular haemoglobin concentration (M.C.H.C.) values were low in both groups, being less than one-third in 29%, but there was no significant difference between the two

interrupting their continuity with the bladder, as a first stage. After the lapse of about three weeks the ureters are divided a short distance below the site of the implant and the upper end is tucked into the colon through a small incision in its wall. The object is to allow the ureter to get over the stage of oedema and constriction due to its inclusion in the wall of the bowel and also to obtain a new blood supply from adhesions before it is subjected to the risk of infection from faecal contamination.

The method seemed so sound and reasonable that I decided to try it. My first case was in 1946, and I have now done six cases in all, with no operative mortality. The number of cases is of course very small, but they are all that I have seen in the interval, and I believe the operation can be performed with a good chance of success by any general surgeon.

The Operation

It may not be out of place to give a description of the operation. I have used a right paramedian incision extending a little above the umbilicus. The bladder is first examined and the question of operability decided; then the left ureter is found on the posterior abdominal wall and isolated for a few inches. A convenient part of the lower colon is chosen and an incision made through the peritoneal and muscle coats down to the mucous membrane.

The size of the ureter varies considerably in these cases, but usually an incision about $1\frac{1}{2}$ in. (3.75 cm.) in length and slight separation of the divided muscle coats are sufficient to make a comfortable bed for it. It is very important that the area should be properly peritonized. A similar procedure is then carried out on the right side and the abdomen closed.

There may be anuria or a very diminished quantity of urine for 48 hours following the operation, but after that the flow is normal. In most cases the patient will have been on urinary antiseptics before operation, and these should be continued when the flow is restored.

In all my cases there has been considerable trouble after this stage from abdominal distension and tympanites, which may last up to a week or ten days before the bowel regains normal function. A most important benefit of the operation is that this phase is passed before the ureter is opened into the bowel.

The second stage is best done three weeks later, and for the last of these weeks the patient is given a course of sulphasuxidine or some similar drug. At the second operation the abdomen is opened through the same incision, which is now carried down to the pubes.

Again I am accustomed to do the left side first. The peritoneum is divided over the ureter so as to expose it just below the implant and is cleanly divided about $\frac{1}{2}$ in. (1.25 cm.) below this. A small incision is made into the lumen of the colon as close as possible below the implant and the upper divided end of the ureter passed into the bowel, which is then sutured round it. A little sulphanilamide powder is rubbed into the area and the peritoneum is closed over it. The right side is treated in a similar fashion.

If the bladder is considered to be removable the cystectomy is then carried out. This is largely extraperitoneal, although it is usually better to include the peritoneum over the site of the tumour. The pelvic peritoneum is reconstituted and the space below drained through a separate suprapubic stab wound. The abdominal incision is then closed. There is remarkably little upset following this stage, considerably less than after the first one. Although there is some discomfort from the urinary incontinence, this seldom lasts more than a few days.

Case Histories

Case 1.—A man aged 38 had papilloma of the bladder treated by diathermy in 1942. Cystoscopy was done at intervals, and the bladder was clear until 1944, when he was found to have multiple papillomata. He continued to have attacks of haematuria until 1946, when I first heard of the present operation. On July 17, 1946, the first stage—implantation of ureters—was performed. The second stage, including cystectomy, was carried out on Aug. 14. Although the bladder was an almost solid mass of papillomata the pathological report was: "Histological appearances are still those of an active papilloma and not of outspoken carcinoma." When last seen, in April, 1948, he complained of some pain in the left renal area. The blood urea was normal, and nothing was found except tenderness in the left loin posteriorly.

Case 2.—A man aged 48 had had haematuria for two months. On Oct. 30, 1946, cystoscopy showed carcinoma above the right ureter. The first-stage operation was done on Nov. 4. A mass on the right side of the bladder was fixed to the pelvic wall—doubtful operability. On Nov. 25 the second stage, including cystectomy, was carried out. The growth was adherent to the pelvic bone and had to be scraped off it. The pathological report was: "Anaplastic carcinoma, mainly of squamous type, infiltrating the muscle." This man did very well so far as the transplantation was concerned, but two months after the operation he complained of severe pain in the right hip. A radiograph taken on March 2, 1947, showed destruction of the right acetabulum and internal dislocation of the femur. He died a few weeks later from local recurrence of growth. There were no renal symptoms.

Case 3.—A man aged 60 had had haematuria, dysuria, and frequency for two weeks. Cystoscopy showed carcinoma of the bladder—several tumours. At the first-stage operation on Feb. 5, 1947, the bladder was considered removable. The second stage and cystectomy were carried out on March 3. The pathological report was: "Anaplastic squamous carcinoma involving the muscle of the bladder. The three apparently separate masses have the same structure." He remained quite well for 14 months after the operation and then developed spinal secondaries. He had no renal trouble up to the time of his death.

Case 4.—A man aged 45 had had attacks of dysuria and frequency for three years. On Dec. 12, 1945, cystoscopy showed a good deal of cystitis, a neoplasm to the left of the trigone, and what I thought looked like tubercles scattered over the bladder. Although I was not aware of it at the time, these were really the vesicles of cystitis cystica. He had been in a sanatorium for some months after a spontaneous pneumothorax in 1933. No tubercle bacilli were found in the urine and the pyelogram was normal except for some dilatation of the ureters. At the first-stage operation on Jan. 13, 1947, there was thickening of the bladder wall over the site of the tumour, but operation was considered to be possible. The second stage and cystectomy were carried out on Feb. 2. The pathological report was: "This bladder exhibits cystitis cystica and also carcinoma." In this case, as in the previous one, there were multiple growths. When seen in November, 1948, he was perfectly well and free from symptoms.

Case 5.—A woman aged 63 had a recent history of haematuria and dysuria. On April 25, 1947, cystoscopy showed a large papilloma of the bladder at the right base and several seedling growths round it. A fragment of the growth was sectioned by diathermy, and the report stated: "Fragments suggest papilloma. I see no histological proof of malignancy." There was a good deal of reaction after the diathermy, and when cystoscopy was carried out on May 12 I decided to leave her for another month. At that time I was very suspicious of malignancy, and a further portion, removed by diathermy, was sent for section. The pathological report stated: "The appearances are deemed consistent with a malignant papilloma." At the first-stage operation on Aug. 11, 1947, the bladder seemed quite operable. The second stage and cystectomy were done on Sept. 1. The pathological report was: "The tumour is a well-differentiated transitional-cell carcinoma. The adjacent mucosa shows an active chronic cystitis with early changes of cystitis cystica." In November, 1948, her doctor reported that she was very well and had no complaints.

Case 6.—A woman aged 56 was seen on March 4, 1948. She had a history of carcinoma of the cervix treated with radium three years before. For the past year she had had severe intractable cystitis with haematuria at times. When cystoscoped as an out-patient there was so much pus that the bladder wall could not be seen. She was admitted to hospital, and after a week's treatment was cystoscoped again. There was a large ulcer of the bladder base, which appeared malignant. As her general condition was good and she was getting so much trouble from the cystitis I decided to do an exploratory operation and see if there was any chance of a radical removal. At the first-stage operation on May 18, 1948, a dense mass of scar tissue was seen round the cervix, including both ovaries, and adherent to the rectum behind and the bladder base in front. At the second stage, on June 8, cystectomy and hysterectomy were performed. The operation was very difficult; the only pleasant feature was not having to worry about the lower ureters in doing the complete hysterectomy. Repair of the lower peritoneum was also difficult after such a wide excision, and was no doubt responsible for the unusual degree of abdominal discomfort and distension which the patient had after the second stage. The pathological report stated: "Cervix: large white mass in cervical wall consists of dense and partially hyalinized fibrous tissue. Both ovaries replaced by a compact mass of dense fibrous tissue. Bladder: the transitional epithelium is somewhat heaped up in places but there is no evidence of invasion. The subepithelial tissue is oedematous and there is a considerable amount of round-celled infiltration of the plasma-cell type, the result of chronic irritation." Although no malignant cells were found I think this was at least a precancerous condition. In November, 1948, she was quite well except for attacks of very severe constipation.

Summary

Six cases with malignant or pre-malignant conditions of the bladder are described. In all the cases transplantation of the ureters was carried out by the method of implanting the ureters in continuity, as a first stage, followed by cystectomy. There was no operative mortality.

Medical Memoranda

Cancrum Oris Among African Natives

The classical description of cancrum oris as given by Christian (1938) is that of a rapidly progressive gangrenous stomatitis in a child already debilitated by another disease, usually one of the exanthemata. Varying treatments are advised, but the prognosis is regarded as hopeless, though Thomson and Findlay (1933) state that occasional recovery does take place. Tidy (1939) states that death is almost invariable. All authorities seem agreed that the probable cause is a combination of organisms similar to that found in Vincent's angina—i.e., spirochaetes and fusiform bacilli. The fact is stressed by all writers that cancrum oris is essentially a rare disease, though I have been unable to find any actual incidence figures.

Observations in Africa.—During the years spent as student, house-surgeon, and general practitioner I did not encounter a single case of cancrum oris in Britain, despite the fact that the whole of this period was spent in a highly industrialized area where the children were often poorly nourished and often lived in unhygienic conditions. In contrast, in less than three years in the Serenje district of North Rhodesia we have come across no fewer than five cases. In the years 1945–7 cancrum oris patients constituted 0.7% of admissions. In no case has there been a previous history of a specific illness. It would seem, therefore, that the main aetiological factors responsible for this comparatively high incidence are the bad diet of the African native and his unhygienic mode of life. It is also worthy of note that the probable causal organisms of cancrum oris are similar to those which are almost invariably found in tropical ulcer, a disease that is always present among the people of this district. Of the five cases seen three were fatal. Of the two who recovered one was treated by extensive resection of the gangrenous area, followed by plastic repair; the other was

treated with penicillin, and this case is detailed below. In no instance did the clinical appearance or progress of the disease differ from the usual description.

Penicillin Therapy.—As favourable results were obtained by penicillin therapy in cases of Vincent's angina it seemed natural to hope that similar results might follow the use of penicillin in cases of cancrum oris. The rarity of the disease, however, seems to have made it difficult to procure reliable information. Fish (1946) was unable to quote any cases. However, a very detailed case history has since been published by Shrand (1947). The case history below is published in the hope that it may add to the volume of information regarding the treatment of one of the most terrible of all children's diseases. It is regretted that circumstances made it impossible to produce more than a purely clinical case history.

CASE HISTORY

A female MuLala child aged about 2 years was admitted to Chitambo Hospital from an outlying dispensary on Oct. 3, 1947. On clinical examination a typical early cancrum oris was seen. The angle of the lip was ulcerated and further investigation showed the ulcer extending back on to the gum in the right canine fossa. There was a well-marked area of brawny induration of the right cheek, extending back to the anterior border of the masseter muscle. Temperature 100.4° F. (38° C.). No history of previous illness could be elicited from the parents.

The following day a brother of the above, a male MuLala child of about 4 years, was admitted with a very advanced cancrum oris. The lips, nose, and most of the right cheek had disappeared and been replaced by a single large sloughing ulcer. Temperature 98.4° F. (36.9° C.). This patient was obviously moribund, and died within twenty-four hours of admission. The virulence of the disease process may be judged from the statement of the parents that the first sign of disease in the boy had occurred only five days previously and in the girl three days previously.

In the case of the female child palliative treatment was adopted. The ulcer was swabbed four-hourly with a strong solution of potassium permanganate, and an attempt was made to maintain the child's resistance by feeding it on thin gruel. Despite these measures the ulceration continued to progress. On Oct. 10 a supply of penicillin became available and treatment with it was instituted, 10,000 units in aqueous solution being administered intramuscularly every three hours. The swabbing with potassium permanganate was continued. After the third injection treatment was interrupted for twelve hours owing to objection from the parents for superstitious reasons. Injections were then resumed, and were continued until 500,000 units had been given.

Results were apparent after twenty-four hours. The brawny induration of the cheek began to soften and the line of demarcation became much less apparent to palpation. After thirty-six hours the sloughs of the ulcerated area began to separate, leaving a granulating surface. After three days of treatment all signs of infiltration of the surrounding tissues had vanished and the ulcer presented a clean and obviously healing surface. Recovery was uninterrupted, and the child was discharged on Oct. 27.

COMMENT

The above case history is interesting in that it records two cases in one family at the same time. There may have been a common source of infection, but it is more probable that the male child, with a highly virulent disease, infected the other. This may indicate a degree of infectivity that does not seem to have been stressed in the literature. This case also indicates that cancrum oris should join the group of conditions classed as highly responsive to penicillin therapy. It was astonishing to see a condition so notoriously fatal, and which had already killed one member of the family, respond so rapidly to penicillin, supported only by the simplest of local measures.

General Blackham was for many years the only representative of the medical profession on the Common Council until 1941, when he was joined by Dr. Westerman, the medical officer of the Charterhouse.

Reviews

MEDICAL EMERGENCIES

Emergencies in Medical Practice. Edited by C. Allan Birch, M.D., F.R.C.P. Compiled by 18 Contributors. (Pp. 468; 113 illustrations, 8 in full colour. 25s.) Edinburgh: E. and S. Livingstone. 1948.

What constitutes an emergency is, as Dr. Birch says in his preface, a matter of opinion, and the word has received an unusually liberal interpretation in this book. It might be contended, for instance, that polycythaemia and amenorrhoea could seldom merit this description, and many of the most useful sections of this work are open to the same ungenerous criticism.

Dr. Birch has recruited eighteen contributors who have together compressed much recondite information into a small compass. Among the more conventional sections, the editor's own description of the management of abdominal catastrophes and Dr. Avery Jones's account of gastro-duodenal haemorrhage are noteworthy. Dr. Rae Gilchrist contributes an excellent discussion of cardiovascular emergencies—perhaps the most commonly encountered in practice. Dr. Murgatroyd's section on emergencies in tropical medicine is particularly useful, for these are often fulminating and often unfamiliar to the practitioner in temperate climes. Descriptions of medical emergencies at sea and in the air are welcome additions to a book of this kind; there are directions for emergency baptism, for broadcasting for relatives of the dangerously ill, and for obtaining supplies of antivenene. The final chapter gives an account of the common practical procedures, the reader having been instructed in an earlier one in the treatment of mishaps resulting from them. In short, there are to be found here answers to the many problems which arise suddenly and unexpectedly in the daily practice of medicine, and only a commendable modesty can have prohibited Dr. Cheetham from including this work itself in his list in Chapter I of the essential contents of the practitioner's emergency bag. The book is excellently produced, and by present-day standards is cheap at the price of 25s.

R. BODLEY SCOTT.

TEXTBOOK OF ENDOCRINOLOGY

Lehrbuch der Inneren Sekretion. By F. Verzár. (Pp. 610; 80 illustrations. 52 Swiss francs.) Liestal, Switzerland: Verlag Ars Medici Lüdin A.G. 1948.

Most recent books on endocrinology have come from America and have inevitably reflected the enormous amount of work on hormones which has been carried out in the U.S.A. during the past twenty years or so. Professor Verzár's new textbook of endocrinology brings, for a change, a Continental point of view. His position in Switzerland has allowed him to select and bring to our notice work which is apt to be missed in Britain, particularly work that was published during the war.

Professor Verzár has chosen the usual method of treating each gland individually, and in separate chapters he describes the general anatomy and histology of the gland, the results of its removal, the methods of isolating its hormones, and their chemistry. He then discusses how the production of the hormone is regulated and the interrelations with the other glands. He describes in some detail the methods of bio-assay. Finally he considers clinical conditions of over- and under-function. Throughout he emphasizes the biochemical rather than the morphological aspect of the subject.

In the introduction he explains that he has tried to select what appear to be the most important findings up to 1945-6 rather than to confuse the reader with a maze of contradictory reports of varying significance. The attempt is successful, and any alterations in emphasis that might be suggested now are an indication only of the speed with which new information on the subject is becoming available. He gives prominence to Mansfeld's claims to have isolated thyroid hormones which stimulate red blood cell formation and which oppose the action of thyroxine, and describes Bomskov's much disputed work on the thymus in a chapter on this gland which, while longer than usual, is certainly justified.

Professor Verzár is widely known for his work on the relation of the adrenal cortex to phosphorylation processes. In his

review of the function of the cortex he favours the belief that there are not separate types of cortical hormone independently controlling water and electrolyte metabolism or carbohydrate metabolism, but that all cortical functions can be carried out by one hormone. Taken as a whole, the book is an excellent summary of the general position in endocrinology. The chapters on the endocrine functions of the gonads are, however, rather unsatisfactory and incomplete, partly perhaps because the author has deliberately omitted any discussion of the gynaecological aspects. It is unfortunate, too, that the illustrations in an otherwise well-produced book should be so few and of rather poor quality.

P. L. KROHN

EXAMINING THE LUNGS

Procedure in Examination of the Lungs, with Especial Reference to the Diagnosis of Tuberculosis. By Arthur F. Kraetzer, M.D. Third edition, revised and with a preface by Jacob Segal, M.D., F.A.C.P., F.C.C.P. Oxford Medical Publications. (Pp. 150; illustrated. 18s.) New York and London: Oxford University Press. 1947.

The intention of this book is to provide for the student a detailed account of physical examination of the lungs "with especial reference to the diagnosis of tuberculosis." After an adequate account of the techniques of inspection, palpation, percussion, and auscultation and of the findings in the normal chest, the author discusses the interpretation of abnormal findings. Each individual variation from normal, such for instance as diminished breath sounds or rales, is tabulated in relation to other symptoms and signs in an attempt to provide a sort of key by reference to which the diagnosis may be reached. In so far as this provides a reasonable scheme for the interpretation of unequivocal signs it may perhaps be useful, even though its validity as an indication of the actual mode of thought of the experienced physician may well be doubted. It is in the emphasis which is placed throughout the book on physical examination as a means of early diagnosis of pulmonary tuberculosis that a curiously old-fashioned and unrealistic impression is given.

Experienced physicians have recognized for many years that minimal tuberculous lesions of the lung often give rise to no physical signs by which their presence can be detected and that radiography is the surest means of detecting them. This truth forms the basis of all modern schemes of tuberculosis case finding; but the unfortunate medical student who took this book as his guide would obtain the impression that unless he could diagnose by physical signs the presence of small tuberculous lesions in the lungs his technique, his mental processes or both would be at fault. The author's attitude towards radiology may be exemplified by two excerpts. On p. 83 he recounts a case of non-tuberculous pneumonia erroneously diagnosed as first as tuberculous, the error eventually being shown by the unexpected clearing of radiographic shadows. In commenting on this he remarks, "The patient should never have been sent for x-ray examination, with its attendant exposure and risk of spreading the disease." On p. 106 he states that pleural and pulmonary rales may be distinguished "by the history, by the symptoms, by the presence or absence of clubbing of the fingers, by the patient's general health, and alas! [sic] by the x ray."

The literary style is presumably intended to be stimulating and to hold the interest of the student, but to the reviewer it seemed a curious mixture of pretentious verbosity with, in places, an almost distressing jocularity. The barbarous solecism (which is unfortunately becoming more and more frequent) of using the word "pathology" as synonymous with "disease" or "lesion" recurs—e.g. (p. 47), "Normal breath-sounds do not rule out pathology by any means."

That physical signs play an essential part in the diagnosis of pulmonary disease, and that the instruction of students in the methods of eliciting them and in their interpretation is of great importance, no one will wish to deny. Physical and radiographic examinations are complementary, each having its proper sphere. Most physicians would agree that there is a grave danger that the manifest superiority of radiography over physical examination in the diagnosis of minimal tuberculous lesions may lead to the neglect of physical examination in its proper sphere. It is to be expected, however, that an attempt to stimulate the student's interest in physical examination of the chest by refusing to

acknowledge its limitations, as in this book, will defeat its own object. There was a well-known domestic cleansing preparation which advertised itself by announcing that it would not wash clothes. The student's interest in the art of eliciting and interpreting physical signs in the chest might well be stimulated rather similarly by the unequivocal statement that physical signs will not enable a diagnosis of early pulmonary tuberculosis to be made, but have a very great value in many other maladies, including some in which they give information which no other method can give.

The book is a reprint, with limited revision and the addition of a short appendix, of one published first in 1930. Its account of the actual technique of examination of the chest and its instructions to the student on the method of acquiring facility in it are sound and helpful; but even at the date of its first publication it probably presented an unbalanced view of the proper place of physical examination in the diagnosis of pulmonary tuberculosis. It certainly cannot be recommended now.

J. G. SCADDING.

THE NEGLECTED CHILD AT HOME

The Neglected Child and his Family. A study made in 1946-7 of the Problem of the Child neglected in his own Home, together with certain recommendations made by a Subcommittee of the Women's Group on Public Welfare (in association with the National Council of Social Service). Introduction by J. B. Priestley. (Pp. 140. 5s.) London: Oxford University Press (Geoffrey Cumberlege). 1948.

This report of a subcommittee of the Women's Group on Public Welfare considers the neglected child in his own home—that is, before he comes to the stage covered by the Curtis Report. Mr. J. B. Priestley in his foreword commends it as an admirable study of a complex problem, but he notes that no mention is made of those children who, although surrounded by all the luxuries, are left so emotionally insecure that they grow up to be antisocial and provide a major problem in criminology.

The report points out that definite physical cruelty is diminishing but that neglect is perhaps increasing and is due more to fecklessness than to crime. As has been said, stupidity is the sin that is always punished and never forgiven. This involves not only physical neglect but mental neglect and even cruelty, which is not regarded sufficiently seriously unless the child shows definite signs of specific mental illness—as he does only relatively rarely. The sequence behind the cases studied is most often one of mismanagement—poverty, malnutrition, ill-health, apathy. Obviously prison is no remedy for child neglect, though often demanded by the public, and fines are not much better. Removal of the child from the home is the easiest solution but by no means usually the best. It should be possible to put parents on probation and make them enter into recognizances for good behaviour, but they ought to have the right to legal representation when the case comes before the court. Local authorities should promote all cases in the courts, but they should all establish children's care committees with suitable officers and staff. They should establish boarding accommodation in the form of schools, homes, and hostels for children who must at least temporarily be removed from their families.

All secondary-school girls should be taught child welfare, and home-craft and parent-craft should be disseminated by every means—press, broadcasting, cinema, and home visiting. The general public should be instructed in normal child development. More facilities should be devised for preserving the health of mothers of young children, and there should be an extension of child-guidance and general psychiatric services, including the provision of expert psychiatric advice at maternity and child-welfare centres. Rehabilitation centres affording rest breaks and holiday homes to mothers are desirable, when, if possible, their children can accompany them. The provision of home helps, day nurseries, nursery schools, and even of household equipment should be increased. Family case work and experiments such as the Brentwood Recuperation Centre in Lancashire should be extended.

This is a most informative and valuable report and should be studied by all interested in children.

R. G. GORDON.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Poetry of a Peripatetic. By Galen. (Pp. 19. 3s.) Romford: Wilson and Whitworth. 1948.

Verses on many topics by a medical man.

Demonstrations of Physical Signs in Clinical Surgery. Part III. By H. Bailey, F.R.C.S., F.A.C.S., F.I.C.S., F.R.S.E.d. 11th ed. (Pp. 304. 8s. 6d.) Bristol: John Wright. 1948.

In this part the author considers the abdomen and the genito-urinary system.

Enturesis or Bed-Wetting. By R. J. Batty, M.D., B.Sc. D.P.H. 2nd ed. (Pp. 103. 9s. 6d.) London: Staples Press. 1948.

The author has incorporated new material in this edition, especially on the psychological aspect.

Notes on Infant Feeding. By G. B. Fleming, B.A., M.D., F.R.C.P., F.R.F.P.S., and S. Graham, M.D., F.R.C.P.E.d., F.R.F.P.S. 3rd ed. (Pp. 66. 3s.) Edinburgh: E. and S. Livingstone. 1948.

An introductory manual intended primarily for medical students.

The Natural Development of the Child. By A. H. Bowley. Ph.D. 3rd ed. (Pp. 190. 8s. 6d.) Edinburgh: E. and S. Livingstone. 1948.

A guide for parents and teachers. The chapter on adolescence has been enlarged in this edition.

Obstetrics and Gynaecology. By B. M. Willmott Dobbie, M.A., M.B., F.R.C.S., D.M.R.E. (Pp. 358. 20s.) London: H. K. Lewis. 1948.

A short practical account intended specially for the novice in general practice.

The Pharmaceutical Pocket Book. Published by the Pharmaceutical Society of Great Britain. 15th ed. (Pp. 427. 12s. 6d.) London: Pharmaceutical Press. 1948.

An introduction to the practice of pharmacy and a reference book for pharmacists.

Zur Theorie des Typhus Abdominalis. By R. Rössle. (Pp. 28. M.2.) Berlin: Akademie. 1948.

The author elaborates his theory of the part played by allergy in typhoid.

Some Victorian Portraits and Others. By Hilda Martindale C.B.E. (Pp. 106. 10s. 6d.) London: George Allen and Unwin. 1948.

Biographical studies of prominent social workers and reformers. Civil Servants, and others.

Modern Methods of Mental Treatment. By J. W. Fisher. M.R.C.S., L.R.C.P., D.P.H., D.P.M. (Pp. 100. 6s.) London: Staples Press. 1948.

A short guide for nurses.

Mycoses and Practical Mycology. By N. Gohar, M.R.C.S., L.R.C.P. (Pp. 234. 25s.) London: Baillière, Tindall and Cox. 1948.

An introductory handbook for prospective dermatologists and students of tropical medicine.

Zur Hygiene der Arbeit. By F. Vering. (Pp. 38. No price.) Vienna: Wilhelm Maudrich. 1948.

An essay on industrial hygiene.

Behold the Axe. By F. Hernaman. (Pp. 288. 9s. 6d.) London: Staples Press. 1948.

A historical novel about an attack of the Crusaders on Constantinople.

Traitement Chirurgical de L'Otospongiose. By M. Sourdisle. (Pp. 253. 750 francs.) Paris: Masson. 1948.

A detailed illustrated manual for surgeons.

The Search for Health. By D. Stark Murray, B.Sc., M.B., Ch.B. (Pp. 158. 2s. 6d.) London: Watts. 1948.

An exposition for the layman of the causes and treatment of disease.

BRITISH MEDICAL JOURNAL

SATURDAY FEBRUARY 5 1949

CO-ORDINATION OF THE TUBERCULOSIS
SERVICES

The continuous fall in tuberculosis mortality in England and Wales, broken only by the war periods, gives grounds for reasonable hope that the disease can be reduced to insignificance. The causes of this decline are complex and obscure, but all will agree with Dr. C. O. Stallybrass, whose survey of the present position appears as the opening paper in this issue, that the most important is improvement in living conditions, and that this socio-economic factor has been assisted by modern methods of treatment and by the segregation of infectious cases in sanatoria made possible by the National Health Insurance Act of 1911. Knowledge of the pathogenesis of tuberculosis has advanced, and there are now grounds for believing that vaccination with a controlled dose of live tubercle bacilli of attenuated virulence, B.C.G., safely establishes a healed primary focus which will confer a considerable degree of protection against subsequent invasion by virulent organisms. At the same time some eminent authorities doubt the strict validity of the evidence, and the problem must still be looked at with scientific caution. There is now a better understanding of the part played by nutrition and environment in maintaining native and acquired resistance to the disease, and the influence of heredity and race is being reviewed in the light of recent research. Advances in radiology have made it easier to discover early pulmonary lesions, so that it is not uncommon to find a small focus of active disease in an apparently healthy person. In treatment a new era is dawning with the use of antibiotics and chemotherapeutic agents which, as further investigations are made, will change the approach to the problem of controlling the lesion.

Yet in spite of these encouraging signs, which should be more than enough to support an optimistic attitude, there is a feeling among tuberculosis workers that all is not well. In a recent letter to this *Journal* (Dec. 25, 1948, p. 1118) Dr. Lissant Cox has picturesquely described the uneasy path that lies ahead through difficulties which he considers mainly due to the break-up of the old administrative machine—a machine which, in general, worked well and produced results. There is little doubt that he is right when he says that at present the chief danger lies in forgetting the essential unity of prevention, treatment, and care work and in failing to view the patient in the setting of his family and his home environment. The treatment of those suffering from tuberculosis must of course be one of the main concerns of tuberculosis workers; but the protection of the healthy is of equal importance, and much time and

energy have to be put into preventive work if it is to be effective. Nobody can read Dr. Stallybrass's survey without being impressed by the urgent importance of preventing the spread of infection, particularly among young children; the incidence of tuberculous meningitis in infants is a sensitive index of the amount of infection in any community. The systematic search for the infectious case must never be relaxed, however strongly the limelight plays on new methods of treatment. It is therefore somewhat disconcerting to learn that Dr. A. S. Hall (Jan. 8, p. 71) considers there is a danger of tuberculosis officers being lured from diagnostic and preventive work by the more exciting practice of active treatment.

The reorganization of the tuberculosis services under the National Health Service Act has tended to emphasize the clinical side of the work of the chest clinic to the detriment of its other necessary activities. Infection with tubercle bacilli has not only a profound effect on all body tissues wherever the major lesion may be, but it has such social significance that its successful treatment depends on detailed knowledge of the clinical and family history and of the conditions in which the patient lives and works. An essential aid to treatment is an efficient rehabilitation service to assist the patient to overcome both the disablement and the stigma that are so unfortunately and unnecessarily associated with it. Awareness of the importance of tuberculosis to the public health has now led to the assembly of a formidable array of authorities, officials, clinicians, and auxiliaries, all concerned in its prevention and treatment. Health authorities and care committees, regional boards and management committees, medical officers of health and tuberculosis and health visitors, tuberculosis physicians (in dispensaries, mass radiology units, and sanatoria) and hospital almoners—these are all working towards the one desired end, are all aware of the necessity for helping each other, but are hampered by a certain vagueness in the procedure for co-ordination.

Tuberculosis mortality rates have fallen, but the incidence is still rising; and the number of adult cases on the dispensary registers in 1946 was 50% more than in 1938. No doubt this is partly due to more intensive search for early cases, but the situation does not warrant the transfer of the tuberculosis officer's place of work from the dispensary to the sanatorium, for this would be immediately damaging to public health. The sanatorium treatment of patients is better left to those who have made such work a full-time vocation and have had many years of experience. As Dr. Hall writes, "It is on the field of prevention that the battle against tuberculosis will be won." May it not be that the present dilemma that has prompted the query "Whither Tuberculosis?" has arisen because of neglect of the wise counsel of Sir Robert Philip, who centred the campaign against tuberculosis in the dispensary and made it a unit for combating the disease in all its forms? The present tendency to regard the various manifestations of tuberculosis as separate entities, each the concern of a particular clinical department, will destroy the ability of the tuberculosis service to attack the problem from all sides. Tuberculosis is a specialty that is associated with many branches of medicine and surgery, and if our hopes of eradicating the disease are to be realized it is clear that

one administrative authority must, with the agreement of all concerned, co-ordinate the work of those who are engaged in prevention, diagnosis, treatment, and rehabilitation.

GROUP PSYCHOTHERAPY

A number of articles¹⁻³ on group therapy during the last few years and, more recently, books⁴⁻⁶ on this subject have suggested to many medical men that an important new development is taking place in psychological medicine. Certainly group therapy is being increasingly used in psychiatric hospitals and out-patient clinics, and in many of the latter more patients are now being given psychotherapeutic help by this than by individual methods. In a broad sense group therapy may be said to be as old as humanity. Man has always sought the company of his fellows in times of emotional stress, and the commonest way of ensuring that the young person's psychological development will be healthy is to put him into suitable social groups. The term "group therapy," or "group psychotherapy," however, is used for procedures in which help is given to individuals with psychological difficulties through the medium of groups created for this purpose.

Many forces have contributed to this. Most prominent, perhaps, has been the fact that the spread of psychoanalytic thought has created a demand for psychotherapy which has grown out of all proportion to the supply of trained therapists. Practically every trained psychotherapist gets far more requests for his services than he can deal with. The position appears even more disturbing if the psychotherapeutic needs of society are surveyed, for the incidence of neurosis⁷ appears to be such that not enough psychotherapists could be trained to give individual treatment to all who require it. A procedure by which several persons can be treated together is therefore of the greatest value. Apart from this external pressure on the psychotherapists there has also been an internal impetus during recent years towards the therapeutic use of groups. This impetus arises as the logical sequence to those advances in the psychology of character and personality whereby, paradoxically, much of the individuality of the person is shown to be derived not so much from such self-contained forces in the form of instincts as from the history of his relations with others. A striking feature of these developments is the way in which the various types of worker—psycho-analysts, psychiatrists, and psychologists—have been moving in the same direction. Among the psycho-analysts this trend may be observed in an ever greater emphasis on the nature of the "here-and-now" feelings in the doctor-patient relationship—the so-called transference situation—with a theoretical counterpart in a turning towards the importance of the earliest relationships between the child and

his parents, as contrasted with the former more exclusive reliance on instinct theories. From the other workers the remarkable contributions, both in theory and in practice, of Moreno,⁸ Lewin,⁹ and Burrow¹⁰ have emphasized the significance for the individual at all times of the forces in his social field. These developments in psychology may well be part of a much deeper *Zeitgeist* in which, according to social philosophers, our Western mass-society is groping towards a replacement of the ideal of the self-sufficient man by one which takes into account man's deep needs "to belong." It is certainly noteworthy that, whatever the contributing forces, in almost every civilized country during the last few decades more and more emphasis is being placed on the contention that man is a social being and that his individuality as a person is meaningful only in terms of his relations with others. There is a risk that this tendency may be carried too far and that the pressure of the group may hinder the exceptional man from expressing himself in art, philosophy, and science: it is to the exceptional man that civilization owes its highest achievements, men who usually stand aside from what Ibsen called "the damned compact majority."

As would be expected from its complex origin, many methods of group treatment have been described. At one end of an imaginary scale could be the mass-suggestion and inspirational approaches exemplified in Couéism and in the Alcoholics Anonymous movement. There might then be a region containing methods with a greater appeal to reason and which accordingly make much more use of explanations of emotional conflicts by the therapist, with or without subsequent free discussion—in which all the unreasonable forces usually involved are apt to play a prominent part. At the other end of the scale would be the methods of what might be termed the sadder and wiser group. This group, following the psycho-analysts, believes that deep emotional conflicts are not resolved unless their unconscious dynamics are revealed in actual human relationships. The work of Bion,¹¹ Rickman,¹² and Foulkes¹ in this country, and of Slavson and his co-workers⁵ in America, illustrates this point of view. Current work in group therapy is mainly concerned with exploring new methods, with the selection of patients, and with the most appropriate compositions of groups. Slavson and his co-workers⁵ seem to be in favour of more specific groupings of cases than are British workers, but apart from this it is interesting to note the broad similarity between the group methods founded on psycho-analytic principles yet developed independently in America and in this country. The more analytic the method the more is the group allowed to develop spontaneously. The idea of six to nine adults meeting to take part in a free discussion with the aim of relieving their psychological difficulties may readily recall some religious movements of recent years. The therapeutic group, however, is sharply differentiated from these by the presence of the therapist, whose function from the start is to interpret what is happening. By seeing their unconscious motives in action in the ways they feel towards each other as well as towards the therapist, the group members gradually gain insight into their difficulties and hence freedom from the tyranny of the war within their minds. The demands on the therapist and patients

also vary with the method. If the unconscious motives are tackled, the primitive nature of many of these motives must sooner or later be brought into the foreground. Great psycho-analytic skill and experience are therefore required to carry the group successfully through the anxieties and other upsets which may follow. More superficial methods are less disturbing to the patient and demand less skill and training from the therapist; but the fact of their being less disturbing may be because the real nature of the patients' problems is avoided.

It is too soon yet to comment on the efficacy of this new work. Evaluation of psychotherapeutic procedures is peculiarly difficult, and it will be some years yet before careful studies can be reported. There would appear to be grounds, however, from the parallelism between the individual and group approaches, to expect results not unlike those which would be obtained by the corresponding methods with individuals. Group therapy is certainly an addition to the resources of psychological medicine, because it saves the time of skilled psychotherapists and because it has already proved to be a most effective instrument in competent hands for resolving psychological conflict. It may also be useful in the treatment of the psychosomatic illnesses. Another point in its favour is that group therapy can help to dispel some of the mysteries of psychotherapy, for the general physician can join in the group and see the psychological specialist at work. This education could have a far-reaching effect. Few people can be members

of a therapeutic group conducted on psycho-analytic lines without emerging from the experience much more interested in the need for, and more able to foster, good relations in groups. If hospital physicians join in group therapy there will inevitably be an increased desire to apply this experience in the hospital ward, in the out-patient clinic, and in the hospital as a whole. The great importance of this development, however, may lie outside its immediate therapeutic value. No one can deny the enormous gain in our understanding of the individual which has resulted from the work of the psycho-analysts, and it may be that our understanding of the forces that promote cohesion and disruption in groups—involving problems of great urgency to-day—will be similarly illumined by the psycho-analytic treatment of groups.

CLUBBING OF THE FINGERS

Finding the explanation for clubbing of the fingers is the kind of problem which invites the method of armchair deduction: so many diverse facts known about the conditions in which clubbing appears or disappears must surely make some sort of pattern. The most recent theory comes from Mauer,¹ in Los Angeles, who marshals the evidence for "tissue anoxia" as the cause. He puts forward the interesting suggestion that only with warm extremities—i.e., with a rapid blood flow through the arteriovenous anastomoses of the digits, such as Mendlowitz² has shown exists in clubbing—will tissue metabolism be sufficiently high for the fingers to suffer from anoxia. Therefore with

diseases like rheumatoid arthritis, Raynaud's syndrome, and Buerger's disease no clubbing is to be expected. The anoxia itself may be the result either of insufficient lung aeration, of shunts as in congenital heart disease, of altitude, or of met- or sulphaemoglobinaemia. To account for tissue anoxia in septic conditions such as subacute bacterial endocarditis or lung abscess Mauer puts forward an earlier suggestion that "corpuscular sludge" formation (due to the same plasma protein change that brings about a high sedimentation rate) itself hinders the giving up of oxygen to the tissues. "Sludge" is the name given to the long rouleaux formations of erythrocytes within the vessels described by Kinsely³: these clumped corpuscles have a much smaller surface area from which oxygen diffusion can occur than the unclumped corpuscles. Whether this is important in the fingers depends on the quantitative assessment of diffusion gradient, dissociation rate, temperature, and oxygen consumption. The theory implies that the plasma oxygen tension is diminished. Sludging, however, is usually associated with a slowed blood flow rather than a fast one, and may even usher in irreversible thrombosis—preventable with heparin. Unfortunately for this theory, conditions associated with much rouleaux formation—often with visible sludging—such as myelomatosis, are not associated with clubbing, nor was clubbing observed in most of the recorded cases of congenital methaemoglobinaemia.⁴

It will be interesting to see what this theory will lead to. Like others, it fails to account for clubbing in a number of conditions, such as the unilateral clubbing of subclavian aneurysms, the congenital type of clubbing, and that associated with post-operative myxoedema. A problem such as this is often complicated in the same way as detective stories by false clues, and possibly the congenital and familial types of clubbing described elsewhere in this issue by Dr. W. P. U. Jackson, together with the other interesting cases where no associated condition was discovered, should be regarded in this light. That such cases can occur without apparent serious illness is to be noted, but this does not indicate any less need for full investigation. It would have been interesting to know what proportion such "non-significant" clubbing formed of the total number of patients discovered during the same period to have clubbed fingers. It may be that some of these "non-significant" cases may ultimately provide the key to the problem, but at present there seems to be a plethora of clinical clues what is needed is the physiological approach. Apart from the work of Mendlowitz it is remarkable to what small extent the physiological methods introduced into clinical medicine by men like Lewis have been applied to this problem and how few are the physiological clues, compared with the wealth—the frozen wealth—of clinical data

THE "HAEMOLYTIC" CRISIS

Congenital haemolytic anaemia was first accurately described almost half a century ago, and the occurrence at intervals of crises during which the red count fell catastrophically has long been recognized. The cause of these attacks has been and remains a mystery, but their sudden onset in epidemic form among affected members of a single family¹⁻⁴ has suggested an association with some infection. Since the crises occur in the course of a haemolytic anaemia it was perhaps natural to assume that they were exacerbations of the continuous and excessive haemolysis already present, and the term "haemolytic crisis" has become allowed by long usage. Nevertheless it was noted from time to time that there were features which it was difficult to explain on this basis. Blood destruction or loss normal

leads to the production in increased quantities of platelets, leucocytes, and reticulocytes, but in the familial outbreaks referred to one or more of these features was frequently absent. In the majority of cases about which the existing information is adequate it was rare for reticulocytes to exceed 1% for the first week or 10 days from the onset of the crisis, even though after recovery a constant reticulocytosis of 10-15% was a feature of these cases. Josephs⁵ in his studies on haemolytic anaemias suggested that in addition to the haemolytic process there might be some hypoplasia of the marrow, and Dameshek³ thought that the spleen might produce a hormone inhibiting the maturation or delivery of cells to the circulation.

A recent article by Owren⁶ throws much light on the subject. He describes "haemolytic" crises occurring in six individuals, four of whom were members of one family and became ill within a few days of one another. Owren's studies show that in five out of the six cases reticulocytes were absent during the first 10 days, and that a sudden rise occurred between the tenth and twelfth days. Leucopenia, thrombocytopenia, and a decrease in serum bilirubin and urinary urobilin were also noted during the early days of the crisis. During recovery the first event was the development of a leucocytosis, followed by an increase in platelets and finally a reticulocytosis. By good chance one of the patients was fully examined both clinically and haematologically eight days before a crisis developed, and an interesting feature of Owren's paper is the series of seven photomicrographs of this patient's marrow throughout his illness. Before the crisis the marrow shows the typical erythropoietic activity seen in this disease, but red cell precursors are almost completely absent in films taken on the fourth and sixth days of the illness; by the ninth day commencing regeneration of proerythroblasts has begun to be obvious, and within a few days the marrow shows tremendously active normoblastic erythropoiesis. Owren also confirms the observation made by Dacie and Mollison,⁷ who showed that the life span of the erythrocytes in congenital haemolytic anaemia is greatly reduced, being less than 14 days, compared with a normal period of 120 days. Owren confirms this finding and draws the conclusion that if marrow aplasia occurs, even without increased blood destruction, the red cell count will be halved in a week. This is precisely the finding in the case already referred to.

The latest word on the subject comes from Dameshek and Bloom.⁸ They report on seven cases (of which three have already been recorded in the literature³), the last of the series having been most fully studied. They confirm the absence of reticulocytes at the height of the crisis and find in the marrow a nucleated red cell population consisting almost entirely of the most primitive cells—namely, pronormoblasts and basophilic normoblasts. As this "maturation arrest" passes off increasing numbers of later normoblasts are seen and reticulocytes begin to appear in the peripheral blood about the ninth day from the onset of the crisis. There is some evidence from this case and others that there is increased faecal excretion of urobilinogen during the crisis, indicating increased haemolysis. Dameshek and Bloom consider that the various features of the haemolytic crisis might be explained by an extreme degree of hypersplenism, causing simultaneously both excessive

haemolysis and a maturation arrest of the nucleated red cells and thus leading to the extremely rapid development of anaemia. It is clear that much interesting work remains to be done in this condition; in any future investigation, in addition to blood and marrow studies, the measurement of urobilinogen excretion is likely to be of critical value in assessing the true importance of haemolysis in the so-called haemolytic crisis.

HYPERSENSITIVITY TO UVEAL PIGMENT

One of the unsolved problems of ophthalmology is the aetiology of sympathetic ophthalmia, though diligent attempts to find the answer have been made for over a hundred years. Stimulus was given to the search when Elschnig,¹ of Prague, propounded his theory of anaphylaxis, a direct outcome of which was the intracutaneous test for hypersensitivity to uveal pigment. Experimenting with this test in 1934 Friedenwald² found that two weeks after injection of the pigment into the skin of a hypersensitive individual the histological findings in the skin—phagocytosis of the injected pigment, lymphocytic infiltration, epithelioid and giant-cell systems—were closely similar to the histological picture of sympathetic ophthalmia in the eye. Woods³ had been working along the same lines for some years before this, and he and McPherson⁴ have recently published the results of some further experiments carried out at the Wilmer Ophthalmological Institute of the Johns Hopkins Hospital. In the interpretation of the tests they chiefly rely on the histological findings in the excised skin.

The pigment solution which they use is derived from the uvea of fresh ox eyes. An injection of 0.1 ml. of the solution is made into the forearm, and in due course the area of the skin is excised and prepared for histological examination. Control studies were also made. The test was considered to be positive when it was found that all the pigment had been ingested by phagocytes and when the skin had been infiltrated by lymphocytes, epithelioids, and giant cells. In some positive cases even nodule formation was observed.

Patients with three different types of eye disease were tested. In the first group were 30 cases of alleged sympathetic ophthalmia, the majority of which were confirmed by histological examination of the excised eye. Of these cases 60% gave straight positive reactions; the remainder were doubtful or weakly positive. In the type of eye injury usually considered most likely to produce sympathetic ophthalmia—namely, that involving the ciliary region of the globe—one of the greatest difficulties for the ophthalmologist is to know how long he can safely wait before deciding to remove the exciting eye. In this country the accepted period is about 21 days. McPherson and Woods concluded from their observations that in the majority of cases in this group the test was positive within the first month. The second group of patients consisted of 139 cases of intraocular operations or injuries involving the uveal tract: there was the usual variation which such cases show in the time and extent of recovery. None of these patients subsequently developed sympathetic ophthalmia, but the pigment-injection tests showed that of those who lost an eye as a result of the injury or operation, or had a stormy recovery with post-operative uveitis, 14% gave a strongly positive reaction. In 13% the results were doubtful and in 66% entirely negative. The third group consisted of 43

cases of endogenous uveal disease. None of these gave positive reactions.

Woods and McPherson believe that the mechanism of these positive tests can be quite simply explained. It has been shown that uveal pigment possesses organ-specific and lacks species-specific immunological properties. When pigment hypersensitivity occurs after an ocular injury the uveal pigment is absorbed from the eye; the cells of the body react to the pigment, and a generalized hypersensitivity ensues. In certain cases, however, absorption of pigment results in a local hypersensitive reaction in the eye with the histological findings characteristic of sympathetic ophthalmia. In those cases in which the result of the test is positive but sympathetic ophthalmia does not occur the mechanism of sensitization is the same, but the process stops when further absorption of pigment from the eye ceases, and no local hypersensitive reaction takes place. The eye is then affected only by a non-specific endophthalmitis. Woods and McPherson suggest one or two possible theories to account for sympathetic ophthalmia, but the problem still remains, and the current theory that the cause may be some obscure infective process activated under certain conditions cannot be discarded. The ophthalmologist may, however, gain some moral support in a doubtful case from a positive intracutaneous hypersensitivity test when deciding upon such a grave step as enucleation.

HEAT AND BLOOD FLOW

It has been a generally accepted axiom that one of the effects of heat is to increase the circulation in that part of the body to which it is applied. Some doubt about the accuracy of this concept has arisen as the result of recent work in the U.S.A. Kemp and his colleagues¹ at the University of Iowa heated the hind limbs of anaesthetized dogs with short-wave diathermy and measured the rate of flow in the femoral artery and vein by means of a bubble

flow-meter. They used a thermocouple to measure changes in the deep temperature, and they found that short-wave diathermy producing a definite rise in muscle temperature failed to increase the blood flow in either artery or vein. In fact they state, "In many experiments a significant decrease in the volume of blood flow was observed." The anaesthetic was not found to be responsible for this result, and a decrease of blood flow on the application of short-wave diathermy also followed if the limb had been previously denervated. On the other hand, heating by means of microwaves according to the technique worked out by Krusen and his colleagues² was found to result in an increased blood flow. Kemp and his colleagues make it clear that their findings refer only to the circulation in the main artery and vein and not to the collateral circulation. In addition their results might have been affected by the anaesthesia, the use of heparin as an anticoagulant, and the sectioning and cannulation of blood vessels. In discussing the contradictory results of heating with short-wave diathermy and with microwaves they suggest that these thermogenic agents may have other effects besides heating. Possibly short-wave diathermy causes an increase in peripheral vascular resistance due to increased sensitivity of the contractile elements in the blood vessels. Thus the beneficial effects of this form of treatment may be due to a decreased rather than an increased circulation. It is also possible that the findings in the anaesthetized dog may not be comparable to those in spastic states of the vasomotor and skeletal systems.

The effect of diathermy on the blood flow in the forearms of normal men has been studied by C. S. Wise,³ of the Harvard Medical School. He measured the blood flow by means of a plethysmograph and used both condenser field and induction cable application of diathermy: with both methods he obtained evidence of increased blood flow in the limb. He concluded that this was the result of the thermal effects of the short waves and not of any specific effect on the blood vessels. Wise was aware of the contrary results obtained by Kemp and his colleagues, and to account for the difference he suggests that the flow in the femoral artery may not be an accurate indication of the flow in the limb as a whole, and also that the flow in peripheral vessels may be increased while that in the central vessels may be decreased. These two papers are of great interest. While the authors of both agree that deep heat is a valuable therapeutic agent they are not agreed on the mechanism by which its effects are obtained. Work such as this will lead to a more exact knowledge of the physiological and therapeutic effects of physical agents.

BONE GRAFTS

During the years after the war much valuable experience has been gained in military and other hospitals as the result of the large numbers of bone-graft operations done to secure union in difficult fractures. A follow-up study on 358 cases has recently been carried out by Bishop, Stauffer, and Swenson¹ in order to determine the indications for the use of the various types of bone grafts. The injuries for which treatment was required were mainly severe gunshot wounds of the extremities, and full-thickness skin grafting was necessary in 21.2% of these cases before bone replacement could be attempted. Union was judged on the clinical and radiological findings. Inlay grafting, which was used at first, was steadily replaced by massive dual onlay grafting, since this was found to be more effective. The procedure was to strip the periosteum off the bone ends in order to provide a continuous sheet; the fibrous tissue between the bone ends was then removed, and the latter were freshened. The marrow cavity was cleaned out with a curette in order to promote endosteal bone formation. The gap between the bone ends was packed with cancellous bone from either the upper tibia or the iliac crest, and massive dual onlay grafts were fixed rigidly in position by machine-type screws, which were considered essential in order to allow early joint motion at the sixth week. Where additional strength was required, plates and screws were used, but never as a substitute for bone grafts.

Of the patients in this series 10.9% had inlay grafts, 40.2% had onlay grafts, and 48.9% had grafts of the dual onlay type. In 318 cases the grafts were followed to union, the average time being 20 weeks. The slowest to heal were inlay grafts, averaging 27 weeks; onlay grafts required on an average 20 weeks, and the dual onlay variety only 19 weeks. Factors causing delay in union were decalcification of bone ends, sclerosis of the major fracture fragments, large bone defects which had to be bridged, infection, poor apposition, fracture of the graft, and poor fixation of the grafts in defects near a joint. Some failures also occurred with short grafts. It is claimed that adequate fixation of the grafts with screws will allow movements at the adjacent joints at an early date and will thereby diminish the time required for rehabilitation. In general the authors regard dual onlay grafting as the method of choice, being indicated particularly when decalcification or sclerosis is present, when the bridging of a gap is necessary, and for use near a joint. Rigid fixation of the graft is essential.

THE JOHNS HOPKINS SCHOOL OF SURGERY

HUNTERIAN LECTURE BY DR. JOHN M. FINNEY, JUN.

The Hunterian Lecture, delivered before the Hunterian Society at the Mansion House, London, on Jan. 17, was by Dr. John M. Finney, jun., of Johns Hopkins Hospital, Baltimore, whose subject was the founding and influence of the Johns Hopkins School of Surgery, and especially the work of William Stewart Halsted (1852-1922), the first professor of surgery there. Dr. Finney recalled that 22 years ago his father delivered a Hunterian Lecture at the Mansion House, when his subject was the influence of John Hunter on early American surgery. On this occasion he proposed to speak of Halsted and his pupils, who might be said to occupy the same position as Hunter and his trainees 150 years ago. The foundation of Johns Hopkins practically coincided with the understanding of the bacterial origin of infection and disease and the development of Listerian methods of control.

Halsted was born in New York and trained in the College of Physicians and Surgeons there, graduating in 1877. In 1878-80 he spent two years in Europe and brought back with him many new ideas gained in Continental clinics. He was chosen to organize the services in the newly founded New York Hospital. He was a bold and original surgeon, an inspiring teacher, an omnivorous reader, an extraordinarily hard worker, accepting responsibility as a surgeon for six widely separated hospitals, and at the same time maintaining a "quiz" of 60 or more students at his house. Among other things he was a pioneer in the method of "refusion" of blood. He also carried out one of the earliest operations in America for gallstones; this was performed on his mother in 1882, when he incised the gall-bladder and extracted seven stones. He was a fearless experimenter, and one of his experiments led to personal tragedy. In 1884 he was investigating the use of cocaine solutions in the eye to produce anaesthesia of the conjunctiva and cornea. He and two of his assistants experimented upon each other and found that pain impulses could be abolished—the first demonstration of nerve-block anaesthesia. Several of the students in the "quiz" were gradually included in these innocent experiments, but the unfortunate outcome was the creation of a group of cocaine addicts, amongst them Dr. Halsted, and Halsted alone seemed to have returned again to a useful though much altered life. After great efforts he freed himself so far as cocaine was concerned, though there seemed to be evidence, said Dr. Finney, of some dependence on small but not increasing doses of morphine during the rest of his life.

He emerged from these trials a greatly changed man. He had been a restless and tireless worker, spending himself in endless operations, teaching day and night, controlling services in several hospitals; but after this interval he began to live a much more thoughtful and leisurely life, with time for reflection and contemplation, and no doubt in the end his work was far more fruitful than it could have been had he proceeded at his previous pace. In 1886, knowing of his struggle, Dr. W. H. Welch invited Halsted to work in his laboratory at Baltimore. Halsted devoted himself to operative procedures and the treatment of wounds, making careful microscopical studies of wounds, paying attention particularly to exact approximation of surfaces and the avoidance of dead spaces, and studying also the organization of blood clot.

Professor on Probation

Although his personal battle against drug addiction had not been quite won when the Johns Hopkins Hospital was opened in 1889, Halsted was chosen for the chair of surgery, for a time on a probationary basis. Within three years he was recognized as surgeon-in-chief of the hospital, and this for him personally was as great a triumph of will power and fortitude as of surgical ability and skill in investigation. Dr. Finney gave an amusing account of the laconic interview with Halsted at which his father was informed that he had been selected as surgical assistant, also of the elder Finney's reactions on going from Massachusetts General Hospital, which was rich in tradition, to the Johns Hopkins, which had no tradition at all but was looking very eagerly into the future.

Halsted was not a very skilful operator, lacking dexterity in the use of his hands, but he made up for it by his intellectual grasp of the principles of surgery and his meticulous care for detail. In his treatment of the staff he was an individualist, insisting on each man carrying out his own investigations with as little assistance as possible. He encouraged his assistants to go into the laboratory as well as into the ward. Shortly after the opening of the hospital he made a striking contribution to surgical technique. In the winter of 1889-90 the nurse in charge of his operating room complained that the solutions of mercuric chloride produced a dermatitis on her arms and hands. Halsted gave the matter consideration and got a rubber company in New York to supply a special rubber glove, so introducing this article, though at first only for the protection of the skin, into the operating theatre. The circumstance had a second result: the nurse for whose protection the glove was devised became Mrs. Halsted.

Dr. Finney said that for 23 years his family lived only a block away from the Halsted home in Baltimore, and he could remember seeing again and again Dr. and Mrs. Halsted, he the picture of sartorial perfection, setting out in some state in their carriage. There was an indefinable something about Halsted which set him apart from ordinary people. In all the 33 years in which he was closely associated with the lecturer's father the latter was never completely at ease in his presence, nor did they ever reach any common ground of mutual understanding and real friendship. There was always a stiffness about Halsted which prevented any real cordiality, and that was true of Halsted's relations with all the members of the medical faculty, with the exception of Welch. Polite respect was the rule; personal intimacy was non-existent. Halsted rarely awarded praise—an exception was his praise of Harvey Cushing—and he could be severe in his censure and in the penalties which he imposed. Dr. Finney told other stories of Halsted's peculiarities. All his suits were made in London and ordered several at a time. His personal linen was not only purchased in Paris but sent back to be laundered there. He picked out the hide from which his shoes must be made. His open fires, of which he was inordinately fond, were fed by white oak specially shipped from the Carolina mountains. Was it any wonder that his operative technique was similarly fastidious, that he should spend two hours on the repair of an inguinal hernia, three hours on a thyroidectomy, six hours on an operation on the breast?

But his influence as the maker of a school was far-reaching, and of the 17 men who served as resident surgeons under Halsted 11 attained professorial rank in some medical school, and the same was true of many of his other assistants. It could be said that, thanks to Halsted's influence, there developed a new school of surgery which spread over the country as men trained in it went out to take responsible posts elsewhere. Halsted's own contributions, especially to the radical treatment of cancer of the breast, were classics, but greater than anything he himself did in surgery was his influence on others, on his pupils, and on those whom they in their turn taught.

In some brief discussion following the lecture Mr. Dickson Wright said that it was encouraging that a man of Halsted's angular and difficult temperament should have been able to found such a school. It was clear that a great teacher need not necessarily be an extrovert. Mr. Mortimer Woolf was reminded of Halsted's likeness to John Hunter, though Halsted, of course, had the benefit of scientific methods and institutions. Sir Gordon Gordon-Taylor added a few words of appreciation.

The Northern Ireland Ministry of Health has issued a booklet entitled *The Future Mental Health Service of Northern Ireland* (H.M.S.O., 1s. 6d.) explaining the provisions of the Mental Health Act, 1948. It gives a broad picture of the details required of the authorities concerned in its administration. Mr. William Grant, Minister of Health, explains in a foreword that the passing of this Act is only the beginning: "I should like to assure the people of Northern Ireland, if any assurance is necessary, that both the Northern Ireland Hospitals Authority and my Ministry intend to press forward energetically with the expansion of the Mental Health Service authorized by the Act."

Reports of Societies

AETIOLOGY OF DENTAL CARIES

At a meeting of the Section of Odontology of the Royal Society of Medicine on Jan. 24 there was a discussion on the aetiology of dental caries. Dr. SHELDON FRIEL was in the chair.

Mr. G. J. PARFITT spoke of this as a debatable question. Was the important factor the physical properties of the food or the structure of the teeth? Was only one factor concerned or were there many? The study was complicated by the varied manifestations of caries, differences in the speed of the process, the fact that all the members of some families were free while in other families there seemed to be a general susceptibility, the higher incidence among town dwellers, the special liability to caries of persons working in certain occupations, and the appearance or increase of caries among primitive peoples on coming in contact with civilization. All this suggested that a diversity of factors were concerned.

If diet was accepted as having an effect on incidence, was this a nutritional effect or was it due to the contact of certain food substances with the teeth? A correlation between caries and variations in the contents of the saliva had been shown by some workers; others had suggested that there was little correlation. The chemical and physical properties of the saliva seemed to have some effect, but did not explain susceptibility or immunity. One curious circumstance was that during the war the children of the Channel Islands who remained at home suffered from caries only to about half the extent of those who were evacuated to England and lived on English food; the latter had caries to about the same extent as English children. It had been shown that supplementary foods for expectant and nursing mothers might prevent caries in the offspring, but no extravagant claims could be made. Experiments in Oslo showed that with antenatal care of the mother and care during the pre-eruptive stage (the first year) of the child's existence there was less caries or more delay in the appearance of caries than among children who had received only post-eruptive care. Ingestion of fluorine in drinking-water during tooth formation was thought to diminish the likelihood of caries, but there was no effect after the teeth had formed. Ingestion of calcium phosphate or vitamin D was declared to have some effect on the teeth after eruption. Some workers had reported an arrest of dental caries and an almost complete suppression of caries incidence in children on a controlled diabetic diet. Some considered that ample ingestion of protein was essential to give protection against caries. An adequate supply of vitamin C was at one time thought to reduce caries by 50%, but further trials did not support that view.

Effect of Carbohydrates

In considering the local environment the question of food left to stagnate in the teeth was an important one. The site, number, and size of the stagnant areas, the influence of mastication, and the arrangement and occlusion of the teeth had to be taken into account. With highly refined foods the scouring effect was missing, and mastication was less vigorous. Methods of preparing food which induced stickiness and a liability for particles to remain about the teeth were contributory. A considerable degree of acidity could exist in the mouth and etch or soften the enamel. But although caries commonly occurred in the areas of stagnation, not all stagnation areas became carious. Sugars had been considered bad for the teeth, and the idea that refined carbohydrates were connected with the production of dental caries had many points in its favour. Bakers and confectioners exposed to refined carbohydrate dust were said to show a high incidence. When consumption of refined carbohydrates was reduced, as in wartime, the caries incidence also was reduced. Refined carbohydrate was an accessory cause which could not be ignored.

As for the bacteriology of dental caries, a vast number of different bacteria were commonly present in the mouth, and many organisms in pure culture produced acid by fermenting carbohydrates. Observations showed that the presence of the lactobacillus was correlated with the carious process, though other organisms took part. Finally, Mr. Parfitt touched upon

the new idea of proteolysis. The fact that the carious process affected the enamel slowly and the dentine more rapidly had been taken to indicate that the process was proteolytic in nature. Amid this crowd of hypotheses he would suggest only that the initial attack on the enamel surface was the all-important matter in the consideration of dental caries.

Professor H. H. STONES said that with present knowledge the theory that the initial stage was brought about by the production of acid still held the field. Why did certain types of persons and certain animals get dental caries and others not? Caries increased among the Eskimo when they came into contact with civilization, but that applied particularly to children and not to those of mature age. He thought that alterations in diet were significant. It was noteworthy that caries was now increasing in Norway, along with increased sugar consumption. He asked whether Mr. Parfitt considered that the small white patches seen on the enamel were a sign of commencing caries.

Dr. A. B. MACGREGOR asked what the "refinement" of carbohydrate meant. It did not mean that there was less carbohydrate. As for sugar, ancient man had caries before sugar was discovered.

Mr. PARFITT replied that white patches on the enamel especially if there was a little roughening or alteration of the surface, generally indicated the beginning of caries. The refinement of carbohydrates meant usually the removal of protein, and with this went a lot of fibre and considerable alteration of substance. Fine carbohydrate was supposed to be much more acid than when mixed with protein, fat, and certain vitamins.

CHEMOTHERAPY OF TUBERCULOSIS

A meeting of the Fine Chemicals Group of the Society of Chemical Industry was held at King's College, London, on Jan. 18 for a discussion on the chemotherapy of tuberculosis. Sir JACK DRUMMOND presided.

Dr. JAMES WALKER said the tubercle bacillus was acid-fast and one of its characteristics appeared to be a relatively high content of lipid material, though there was no evidence of a continuous lipid membrane around the bacillus, a theory which was fairly widespread. A number of metabolic products had been isolated, and one of these, mycolic acid ($C_{80}H_{112}O_4$), was the compound chiefly responsible for acid fastness. But while some of the metabolic products of the tubercle bacillus had been demonstrated, it was not known yet by what metabolic pathways they were produced. The growth of the tubercle bacillus was relatively slow. It was a common experience for recently isolated strains to require to be cultured several times before growing well in the test tube.

Tuberculosis was unlike any of the other bacterial infection with which chemotherapy had to deal. When small number of staphylococci or streptococci were introduced into the body they were dealt with by the phagocytes, and the host was unaware of the incident; the tubercle bacillus could live and even multiply within the phagocytes. With tuberculosis, again the direct method of investigation by going straight to the experimental animal had the disadvantage that the disease had a long course.

Koch reported many years ago that gold cyanide inhibited the bacillus *in vitro* in a concentration of 1:2,000,000, but it had no effect *in vivo*. Not until many years later was this explained by the fact that gold-protein compounds did form in the body. The best-known gold compound was sanocrysin which was introduced in 1924 and was received everywhere with uncritical enthusiasm. Gold had now almost disappeared from the current literature of tuberculosis. Since 1935 the advent of the sulphonamides had redirected the therapy of bacterial diseases generally. The speaker gave a brief review of the work done on the various compounds, concluding with a reference to antibiotics and especially streptomycin.

Clinical Aspect

Dr. P. M. D'ARCY HART said that it was important to discover some order in the use of substances offered for combating tuberculosis. Only a minority of such substances have been found to have any effect on experimental animals, but some which had low or no activity in the test-tube might

be active in the body. The guinea-pig was usually employed for the study of tuberculosis; its disadvantage was that for screening purposes it required a relatively large amount of the drug. The mouse had been used experimentally, but it was generally more resistant to tuberculosis than the guinea-pig. The advantages and disadvantages of extreme susceptibility on the one hand and considerable natural resistance on the other in testing drugs in tuberculosis were being studied. It seemed that the use of guinea-pigs, laborious as the process was, was still the most fruitful method.

He went on to speak of the groups of substances which had been tested recently on experimental tuberculosis in animals or clinical tuberculosis in man with positive results. The first group consisted of the sulphonamides and sulphone compounds. Then came fatty acids, then aromatic compounds, followed by certain miscellaneous organic compounds, and finally the antibiotics. The list included purely synthetic substances, such as sulphones, on the one hand, which had been created in the laboratory, and on the other hand products which so far had not been synthesized and existed only in nature. Only about half a dozen substances had been found to have positive results in clinical tuberculosis in man. Of the sulphonamide group, promizole and sulphethrone were the two most popular at the moment. Another compound fairly widely used was para-amino-salicylic acid. Among the miscellaneous organic compounds was calciferol. The antibiotics included conspicuously streptomycin. He also put in the list of antibiotics cepheanthine, described by certain Japanese workers as almost miraculous in its activity, but, according to a recent report from America, having no activity in the guinea-pig.

For the benefit of an audience mainly non-medical Dr. Hart gave a brief account of tuberculosis and its manifestations, and then examined in turn the various compounds which promised positive results in human tuberculosis. Several hundred sulphone compounds had been tested in the laboratory and a number in man. The clinical results indicated some regressive effect, but he thought it was fair to say that no definite place had been found for these drugs when used alone. The use of the sulphones with streptomycin might be more promising.

Clinical trials with para-amino-salicylic acid had been in progress in Sweden, and there had been a few sporadic investigations in this country. At the moment it would be unwise to come to a conclusion about the value of this drug in tuberculosis. With calciferol dramatic and consistent improvements had taken place in the therapy of lupus vulgaris. The effectiveness of this therapy was discovered simultaneously in France and in this country during the war. It was not clear how calciferol worked; possibly it worked on the host and not on the bacterium.

Streptomycin

The discovery of streptomycin, Dr. D'Arcy Hart continued, was of historical importance because of its low toxicity, which permitted its use in effective doses in animals and man. Streptomycin was water-soluble and yet apparently would pass readily into the cell. It was effective, at least temporarily, in a small proportion of the acute forms of tuberculosis, such as tuberculous meningitis and acute miliary tuberculosis, which had hitherto proved almost invariably fatal. It had a limited effectiveness in renal tuberculosis, but appeared to be of little value in the more chronic forms of lung disease.

Concerning the toxicity of the other agents, promizole might produce after a long period thyroid enlargement and sexual changes. Para-amino-salicylic acid had little systemic toxicity, though the large quantities which had to be taken complicated its use. Streptomycin, though of low toxicity, had the disadvantage that resistant strains of bacilli emerged during prolonged treatment. Attempts to prevent the appearance of such strains had been made by combining streptomycin with other agents, but no conclusive results were as yet forthcoming. The difficulty in assessing the clinical usefulness of drugs in tuberculosis lay in the large doses in which they had to be used in man as compared with experimental animals, the protean manifestations of the disease, its chronicity, and its tendency to natural recovery. Chemotherapy was only one approach to the problem. The older methods of treatment and social prevention had a great part to play. It looked as if the

weapons required for the conquest of tuberculosis were as varied as the pathological manifestations themselves.

In the course of some discussion Sir JACK DRUMMOND said that it appeared that the limiting factor in studies on potentially valuable compounds was the absence of a thoroughly satisfactory screening test less laborious and time-consuming than the guinea-pig test. He had been interested to hear of trials in Sweden on para-amino-salicylic acid, and he asked whether the Medical Research Council intended to make similar tests under adequate control. Dr. HART said that that was being done, and it was also under consideration whether a combination of para-amino-salicylic acid and streptomycin might be of service in preventing the emergence of resistant strains.

Several contributions to the discussion were made by biochemists, one of whom said that there was little doubt that the lipid complex of the organism had extraordinary chemical and physico-chemical properties, with the capacity to inhibit activity over a very wide range of antibiotic substances. The tubercle bacillus would stand 40% sulphuric acid for an hour and 10% for twenty-four hours without being killed. Evidently there was some significant mechanism which prevented quite small ions from getting to the cell.

Another speaker, Dr. O'CONNOR, said that the greatest advances in therapy would come only from much closer co-operation between organic chemists, biologists, and medical men. The organic chemist was often working in the dark owing to his non-appreciation of the biological problems involved. In America organic chemists had made a slight modification of streptomycin, and according to American reports the toxicity of the modified product had been further lowered. Another approach which organic chemists might make to the problem was in devising adjuvants which might be administered to enhance the activity of the principal drug. With para-amino-salicylic acid, clinical trials had shown that within as short a time as three or four days the patient's general condition improved considerably; it looked as if the toxins in his body were to some extent neutralized, so that possibly the natural body resistance was then enabled to cope with the virulent bacteria.

CAUDAL ANALGESIA

At a meeting of the Edinburgh Obstetrical Society on Jan. 12, with the president, Dr. E. CHALMERS FAHMY, in the chair, papers were presented by Dr. A. F. ANDERSON and Dr. J. D. BOURKE.

Dr. Anderson, discussing caudal analgesia, described the anatomical features of the sacral canal. He reviewed the pharmacological effects of local anaesthetic injected extradurally in this region and discussed the interference with such effects resulting from abnormalities of development of the sacrum, of which he showed a number of radiographs. He then recorded his personal introduction to this subject, and indicated how he had concluded that in this country the method should be restricted to hospital practice, and that the constant attention necessary for success with a continuous technique was so exacting as to make it applicable to very few patients indeed. He had therefore decided to restrict his investigations to the use of a single dose using procaine to determine the quantity of anaesthetic necessary to secure the desired effect and then giving a second injection through the indwelling needle of a similar quantity of amethocaine hydrochloride solution with a view to prolonging the effects of the procaine. With this technique he had found it possible to obtain relief of pain lasting from three to five hours. The factor most vital to success was the timing of the injection to allow of delivery occurring within this range. Dr. Anderson described the technique of the caudal injection, and subsequently discussed indications and contraindications. Of the former, he thought the need to relieve pain in premature labour was the most important. He thought the method should be in the hands of an obstetrician or of a specialist anaesthetist with very wide experience of practical obstetrics. He recorded the results of 67 cases personally treated.

Anaesthesia for Caesarean Section

Dr. Bourke discussed the difficulties facing the anaesthetist in choosing an anaesthetic for caesarean section. Many caesarean sections were in patients who were already suffering

from serious disorders peculiar to pregnancy or to parturition, from pre-eclampsia, starvation, and acidosis; from grave ante-partum haemorrhage; or from diabetes, tuberculosis, or other incidental disease. Many were emergencies, where reasonable pre-operative preparation could not be attempted. Many patients were suffering from a degree of gastric dilatation and were liable to vomit large quantities of material suddenly. Sedative pre-medication, which might prejudice the foetus, must be eschewed. Finally, the presence of a large tumour within the abdomen and the insistence of some operators upon a steep Trendelenburg position interfered with diaphragmatic respiration. Spinal analgesia had a sinister reputation, possible reasons for which Dr. Bourke examined in detail. Nevertheless it had certain advantages, and there was a place for it, especially when supplemented by light general narcosis. Inhalational anaesthetics were undoubtedly the most frequently employed. A possible objection was that most general anaesthetics depressed the activity of the uterine muscle. This risk could be minimized by the use of cyclopropane at a very light plane along with curare, which provided necessary relaxation and minimized the total dose of the agent used, so reducing its toxic effect. It appeared that significant quantities of curare did not cross the placental barrier, but not more than 10 mg. should be given. In the series of cases which Dr. Bourke now recorded the results for the babies had been quite favourable, most breathing well at once and all crying within eight minutes. Local infiltration analgesia was indicated in those cases where there was gross foetal distress, when no form of anaesthesia which might affect the foetus, however remotely, should be employed. Caution was required in applying this method to obese patients, who might require such a large infiltration that toxic effects might appear, while wound healing was sometimes poor. The inhibition of sulphonamides by procaine solution had also to be remembered.

These papers were discussed by Dr. JOHN GILLIES, Dr. D. S. MIDDLETON, Dr. W. F. T. HAULTAIN, Dr. R. DE SOLDENHOFF, Dr. SUZANNE PATERSON, Dr. CAROLINE ELLIOTT, Dr. W. I. C. MORRIS, Dr. ALISON RITCHIE, Dr. F. G. GIBBS, and the president.

HARVEIAN SOCIETY OF LONDON

The annual general meeting of the Harveian Society of London was held at Manson House, 26, Portland Place, W.1, on Jan. 19. The Buckston Browne Prize for 1948 was presented to Dr. V. C. Medvei by the president, Mr. E. G. Muir. The honorary treasurer, Sir Cecil Wakeley, made his financial statement and announced that the society had benefited to the extent of £7,250 by a bequest of the late Sir Norman Gray Hill. The president then read his address, "A History of Surgery." New Year greetings were conveyed to the meeting from Professor Sven Johansson, of Sweden, a foreign corresponding member of the society. The officers for 1949 were elected, Dr. Desmond MacManus being inducted as president.

The London County Council has recently published the *Statistical Abstract for London, 1937-1946* (with 1947 figures where available). Information contained in this volume is entirely statistical, and subjects range from infant mortality to liquor licensing, and from horse-cabs to the number of meals served in civic restaurants. Among the items of medical interest relating to the year 1946 are the following: The estimated population in the administrative county of London was 3,109,240, which was over three-quarters of a million more than in 1941. The birth rate was 21.2 and the crude death rate 12.6. The infant mortality rate was 38 per 1,000 live births. "Violence" was given as the cause of death of 141 infants under one year of age. There were 1,622 children attending special schools for physically handicapped children, and 1,823 children attending special schools for educationally subnormal children. The number of voluntary hospital beds was 17,424, and L.C.C. hospital beds, excluding those in mental hospitals, numbered 33,762. There were 620 admissions to hospital for diphtheria; this compares with 6,094 in 1938. There were 379 suicides, compared with 594 in 1938. The total number of patients certified under the Lunacy Acts was 20,604, and there were in addition 2,171 voluntary patients in the mental hospitals. There were 11,651 certified mental defectives. Traffic accidents caused 691 deaths, compared with 1,458 (the highest total ever reached) in 1933. The report reveals that 18,688 civilians were killed in air raids in the administrative county of London during the war.

Correspondence

Haemolytic Disease of the Newborn

SIR,—I should like to express my appreciation of the valuable contribution to the knowledge of haemolytic disease of the newborn made by Dr. P. L. Mollison and Miss Marie Cutbush (Jan. 22, p. 123). This paper demonstrates once more that routine serological tests during pregnancy are absolutely essential, and in addition shows the importance, if the newborn child is likely to be affected with haemolytic disease, of close co-operation between the obstetrician and the paediatrician so that the haemoglobin and bilirubin values of cord blood can be estimated directly the child is born and the appropriate treatment undertaken.

I have always maintained that haemolytic disease of the newborn is a disease of the foetus and not one that "comes on" after birth, even although some of its manifestations become more obvious shortly after that event. I could never, however, explain to my own satisfaction the sudden onset of a severe haemolytic anaemia some days after birth in an apparently normal baby, nor does the explanation now put forward by Dr. Mollison and Miss Cutbush completely satisfy me. According to them, estimation of the cord haemoglobin shows that these infants are actually anaemic at birth and that "in fact the haemolytic process is maximal at birth." I wonder if their observations refer to babies suffering from hydrops foetalis and anaemia and not to those who have haemolytic anaemia of the newborn. I raise this point because in the cases to which they refer death occurred within 24 hours of birth, whereas the infants of whom I am thinking appear normal for a few days after birth and then suddenly develop an intense anaemia which can usually be cured by simple transfusion with Rh-negative blood.

The authors also suggest that "the incidence of kernicterus is closely related to the haemolytic process," but, if this be so, why is there only a trace of jaundice and never kernicterus in this type of haemolytic anaemia of the newborn and in the acute haemolytic anaemia of older children? They quote me as suggesting an opposite view—namely, that there is "an inverse relationship between the degree of blood destruction and the development of kernicterus"—but I have never made that suggestion. What I have said is that I have never found "any parallelism between on the one hand the degree of the haemolysis and on the other the severity of the jaundice and the presence of kernicterus." Dr. Baar and I believe that we have shown that the jaundice in haemolytic disease of the newborn is due to liver damage and that the kernicterus is a sequel of such liver damage and therefore not "closely related" to the haemolytic process.

We believe that the changes in the brain occur during foetal life and not, as the writer of your leading article suggests, after birth, but that in those children who are born unjaundiced the actual staining may not take place until jaundice develops after birth. We have seen kernicterus in a child who died 18 hours after birth, a considerably shorter time than the 2 to 5 days mentioned in the paper.

There is one other point in the paper on which I wish to comment. This is the statement that "it is surprising that so much stress has been laid on blood destruction as a cause of the anaemia to the complete exclusion of any consideration of changes in the amount of production." Actually in our earliest papers on this subject my colleagues and I stressed the fact that this disease was a disease which not only produced haemolysis but also one which affected the erythropoietic centres, and that the purpose of blood transfusion was to tide these centres over their "aregenerative" phase and thus enable them to recover. It was for this reason that we originally spoke of the disease as "erythronoclastic" rather than "haemolytic," thus indicating that the whole erythron was affected. We still hold this view, only now we should add to it that, although erythronoclastosis is the commonest manifestation of the disease, the antibodies also affect the liver and sometimes indirectly the brain, kernicterus being in our view a hepatic encephalopathy.

These criticisms are not intended in any way to underrate the great value of this paper, for which once more I thank the authors.—I am, etc.,

Birmingham.

LEONARD G. PARSONS.

Early Diagnosis of Tuberculosis

SIR,—As a general practitioner I have been particularly interested in the correspondence which followed the publication of Dr. Peter Stradling's paper, "The Practitioner's Part in the Anti-tuberculosis Scheme" (Nov. 6, 1948, p. 832). The purpose of this letter is to draw attention to the usefulness in general practice of testing for tuberculin sensitivity, a simple procedure that can be regarded as complementary to radiography of the chest, and no less important, though its scope and significance are different.

Primary tuberculous infection in children is easy to overlook, because it often appears in such an apparently innocent guise as a brief self-limiting febrile illness, slow recuperation after whooping-cough, or vague ill health without localizing symptoms or signs. It is in such cases that tuberculin skin tests can be so informative and helpful in selecting patients for further investigation in hospital. The tests are quick and easy to perform, and have the additional merit, important in general practice, of being almost entirely painless. My own procedure as a rule is to carry out a jelly test first; then, if that is negative and further precision seems necessary, to do an ordinary intradermal Mantoux test with a 1 in 1,000 dilution. It is important to bear in mind that the result of either of these tests is never more than a pointer.

During the last six months I have tested 19 children on a suspicion of tuberculosis. Among these, 3 out of 18 jelly tests and 2 out of 9 Mantoux tests have been positive. Some illustrative cases are described briefly below.

(1) A girl aged 11. Night sweats for several months. Tired and irritable recently. Mantoux (1:1,000) positive. Radiograph of chest shows a large root shadow.

(2) A girl aged 9. For 10 days P.U.O. up to 103° F. (39.4° C.), characterized by tachycardia out of proportion to degree of fever, but otherwise by remarkably little constitutional disturbance. Tuberculin jelly test positive. Radiograph of chest shows well-marked primary complex.

(3) A boy aged 3. Measles and whooping-cough last summer. Fluctuating enlargement of cervical glands on both sides recently. Fossils unhealthy. Tuberculin jelly test positive. Radiograph of chest normal. Diagnosis probably tuberculous tonsillitis and adenitis with superimposed secondary infection.

(4) A girl aged 10. Tired for a year. Faint in the morning. Overgrown weedy child with marked lumbar lordosis. Tuberculin jelly test positive. Radiograph of chest normal, and E.S.R. 10 mm. Positive test probably a legacy of a past infection and irrelevant to present condition.

(5) A boy aged 3. Poor recovery from whooping-cough, with failure to regain weight; and persistent cough. Bad home conditions. On examination, coarse crepitations over both lower lobes. Jelly test and Mantoux (1:1,000) both negative. Radiograph of chest showed increased markings at both bases. Full recovery at convalescent home.

(6) A girl aged 4. Poor recovery from whooping-cough with repeated coughs and colds. Home very damp. Fragile and pale, but no localizing signs. Jelly test and Mantoux (1:1,000) both negative. Further investigation not considered necessary at this stage. Child kept under observation and improved on symptomatic treatment.

Even this small series of cases gives some idea of the value of the procedure.—I am, etc.,

Oxford.

G. A. BALLANCE

Diagnosis of Tuberculous Meningitis

SIR,—Dr. J. T. Lewis (Dec. 11, 1948, p. 1036) advocates the recognition of lowered cerebrospinal-fluid glucose as an early diagnostic sign in tuberculous meningitis.

A simple clinical test based on this fact has been in use in the hospitals in this area for over 14 years. The reagent employed is a 2% solution of Fehling's A and B. Equal quantities of the reagent and cerebrospinal fluid are taken, boiled, and mixed. A clear cerebrospinal fluid which fails to reduce the Fehling's solution is almost pathognomonic of tuberculous meningitis. The only other conditions in which it occurs are rarely in lymphocytic choriomeningitis and in extremely rare torula infection of the nervous system.

This test and its significance were taught me as a student by Dr. Emrys Harries, lecturer in infectious diseases in the Welsh National School of Medicine, and I have used it on numerous occasions and proved its reliability.

—I am, etc.,

Whitchurch, Glam.

P. T. BRAY.

Amethocaine Hydrochloride

SIR,—Mr. C. A. Jackson's excellent article on amethocaine hydrochloride (Jan. 15, p. 99) serves as a reminder of the lethal potentialities of this otherwise admirable anaesthetic agent. In the thoracic unit of Frenchay Park Hospital prior to bronchoscopy the average premedication is pentobarbital (oral) 1½ gr. (0.1 g.) at 45 minutes, and "omnupon" ¼ gr. (11 mg.) and atropine 1/100 gr. (0.65 mg.) at 30 minutes.

The use of atropine would appear to be desirable, as it is difficult successfully to anaesthetize a mucous membrane which is liberally washed with saliva. In such cases a much larger dose of amethocaine might be necessary. Excess secretion in the bronchial tree renders diagnostic bronchoscopy considerably more difficult, and furthermore, as Langton Hower¹ states, "the passage of tracheal tubes under light general anaesthesia only can give rise to reflex disturbances of the respiratory and circulatory mechanisms." These reflexes, though subdued by topical analgesia to the cords, may still give rise to cardiac arrhythmias and even possibly to cardiac arrest. On the assumption that the reflexes are of vagal origin it would again seem desirable to use atropine as a premedicant.

I usually endeavour to complete the topical analgesia for bronchoscopy with 80 mg. of amethocaine in 2% solution—i.e., 4 ml. of this solution without adrenaline. The operative technique is much the same as used by Mr. Jackson. We do now, however, completely omit the 65 mg. lozenge of amethocaine, as we have found that either the tablet is not dissolved in an atropinized mouth, or else, if it is dissolved, a very inadequate degree of analgesia is produced which cannot be compared with the analgesia we can secure with the same dose—i.e., 3½ ml. of 2% amethocaine—applied deliberately. During the period of use of this lozenge of amethocaine the house-surgeons reported about eight cases of very mild overdosage of amethocaine in about 550 cases, but since abandoning the use of these tablets we have not seen any comparable number of reactions in an admittedly small number of cases.

As regards the use of sprays, it is sometimes of value to direct five vigorous "bursts" of the agent into a graduated vessel, thus measuring the amount projected with each burst. It is sometimes as much as ½ ml. with some sprays, and free use of sprays will therefore readily result in an overdose.—I am, etc.,

Bristol.

T. N. P. WILTON

SIR,—Mr. C. A. Jackson in his interesting paper on amethocaine hydrochloride (Jan. 15, p. 99) makes the following statement: "Application by means of a laryngeal spray should be avoided, as it may easily lead to overdosage." This statement should certainly be qualified, because the amount of solution delivered by a laryngeal spray can be measured, and the use of such a spray is to many the simplest method of anaesthetizing the pharynx and larynx.

The following procedure may be used to calibrate a de Vibiss atomizer sufficiently accurately for practical purposes. An atomizer with a fine nozzle is chosen. Some of the solution to be used is placed in the spray. The number of complete compressions of the bulb necessary to atomize a measured amount of the solution can be found by directing the spray into a calibrated container. When this is known, it is possible in practice to count the compressions used while spraying the pharynx and larynx and thus to know what quantity of solution has been delivered. Two sources of error can arise. First, the bulb may not be fully compressed: this would lead only to less being delivered than estimated. Secondly, the amount delivered by the nozzle might vary over a period of time: this is easily checked.

From the above facts it may be seen that the use of a laryngeal spray need not lead to a risk of overdosage.—I am, etc.,

Bedford

N. WYNN-WILLIAMS.

SIR,—The article on severe toxic effects from amethocaine by Mr. C. A. Jackson (Jan. 15, p. 99) reminds me that I saw a similar case in 1938, in which convulsions followed the (traumatic) introduction of a bougie, 10 ml. of 2% amethocaine having been injected into the urethra. The convulsions were controlled by thiopentone; artificial respiration (by inflation with oxygen) had to be continued for 45 minutes before active respiration returned.

For bronchoscopy I prefer cocaine solution (10 or 15%) to amethocaine, and I believe that the danger of reaction is negligible provided that the drug is restricted to the air passages and be not swallowed or injected into the tissues. I think it likely that this applies to amethocaine also. Mr. Jackson's cases seem to bear this out: in the second it is stated that 2 ml. were thought to have been swallowed; in the first it is not stated whether the tracheal injection was made per glottidem or by external puncture. In the latter case it is comparatively easy to be misled as to the site of the needle, for air will be obtained on aspiration if the needle be ill-fitting, an injection into the tissues resulting. In the former case, solution falling on the walls of the upper part of the larynx may be brought up by a cough and swallowed. For this reason I always try to ensure that the solution be deposited well below the larynx: if per glottidem by a long catheter, if by external puncture by inserting the needle through the first or second ring of the trachea; injection at a higher point is made even more hazardous because the mucous membrane is separated from the cricothyroid membrane by areolar tissue, which increases the likelihood of injection into the tissues.—I am, etc.,

Newcastle-upon-Tyne.

M. H. ARMSTRONG DAVISON.

SIR,—I was interested to read Mr. C. A. Jackson's article (Jan. 15, p. 99) on the above subject. I wish to record two recent experiences using amethocaine as a local anaesthetic in a cachectic patient.

The patient, an elderly woman with ascites following advanced malignant disease, required tapping at frequent intervals to relieve distension and discomfort. On the first two occasions, when amethocaine (4 ml. of a 2% solution) was used to augment a whiff of trilene, the patient became faint and giddy, and finally unconscious with a convulsive seizure. Consciousness returned after about five minutes. These seizures happened while the cannula was *in situ* and after the effect of the trilene had passed. Subsequent tappings using trilene only have been uneventful. It was only after the second time that I became suspicious and decided to use trilene only.

This case confirms Mr. Jackson's advice not to use amethocaine in a cachectic patient.—I am, etc.,

Lydbrook, Glos

M. McMINN.

SIR,—Mr. C. A. Jackson in his article on the severe toxic effects of amethocaine hydrochloride (Jan. 15, p. 99) quotes me as having had two deaths from the use of this drug in gastroscopy. His reference is to the *Proceedings of the Royal Society of Medicine*, 1939, 32, 538.

The reference is perfectly correct, but nowhere in the paper do I state that I had any deaths from the use of "decaine" (amethocaine hydrochloride) in gastroscopy. I reported two deaths during the preparation for gastroscopy, one as having occurred in Minneapolis, the other in this country. I myself, over 2,000 instrumentations, have had no fatalities with the use of this anaesthetic.

Later in his paper Mr. Jackson mentions that the addition of adrenaline reduces the toxicity of amethocaine hydrochloride by one-fifth. I should be very interested to know his authority for this, as the only experimental work that I have been able to trace goes to show that the toxicity of amethocaine and adrenaline when injected intravenously together is much in excess of either separately. For this reason I always advocate the use of 2% amethocaine hydrochloride solution alone.—I am, etc.,

London, W.1.

P. E. THOMPSON HANCOCK.

SIR,—The two cases reported by Mr. C. A. Jackson (Jan. 15, p. 99) of toxic reactions following the administration of amethocaine hydrochloride prompt me to record experiences with this drug in children. For the last ten years 2% amethocaine hydrochloride (no adrenaline) has been used as a local

analgesic for bronchography without toxic effects. Immediately after the insertion of a special needle through the cricothyroid membrane into the trachea the drug was slowly injected through the needle, the quantity, *one minim per year of age*, being carefully measured out and rarely exceeded. When the bronchial tree on both sides was to be outlined the dose of amethocaine hydrochloride was repeated between the filling of the first and the second sides. This second dose usually followed 10 to 20 minutes after the first, when the analgesic effect was wearing off. In about 1,000 bronchograms no ill effects that could be attributed to the drug have been observed.

These observations support Mr. Jackson's final remarks that overdosage or faulty technique is more often the cause of death than individual idiosyncrasy. Although adrenaline was not used in combination in our series, it is probably an extra precaution which should be taken in future.—I am, etc.,

London, W.C.1.

C. ELAINE FIELD.

Treatment of Anuria

SIR,—I was interested to read Drs. D. A. K. Black and S. W. Stanbury's article on the treatment of anuria (Dec. 25, 1948, p. 1101). Their description of a case of anuria caused by incompatible blood transfusion prompts me to record briefly the following case in which anuria occurred during the course of blackwater fever and in which urinary flow was apparently established by intravenous glucose and plasma.

A British N.C.O., aged 31, was admitted to a military hospital in West Africa for subtertian malaria. Next day, whilst on quinine, he complained of abdominal discomfort, appeared shocked, and passed port-wine coloured urine. For the next five days his condition was satisfactory, and the urinary output was in proportion to the fluid intake. Anuria gradually started on the sixth day, and the total urinary output in 24 hours for the subsequent few days was as follows:

Day of Illness	Urinary Output
6th	3 oz. (85 ml.)
7th	1½ oz. (35 ml.)
8th	Nil
9th	6 oz. (114 ml.)
10th	7½ oz. (220 ml.)
11th	13½ oz. (380 ml.)
12th	39 oz. (1.2 litres)

During the sixth and seventh day of illness the patient showed signs of uraemia—viz., mental confusion, drowsiness, restlessness, muscular twitchings, and incessant vomiting. Blood pressure was 110/50, and blood urea 280 mg. per 100 ml. Attempts to establish urinary flow by alkalization and hypertonic sodium sulphate solution failed. On the eighth day he became comatose, with Cheyne-Stokes breathing, and the so-called uraemic "frost" was visible on the skin. Urinary output was nil, and his blood urea rose to 300 mg. per 100 ml. His blood pressure remained unchanged. Blood count showed R.B.C.s 1.48 million per c.mm. and haemoglobin 38%. At this stage 20 ml. of 25% glucose solution was given intravenously, and an hour later he passed 2½ oz. (78 ml.) of urine which was neutral in reaction and contained protein ++, urobilinogen +, bile pigments +, and urea 0.5 mg. Deposit showed epithelial, endothelial, and pus cells. No casts were seen. Encouraged by this result I decided to put him on glucose and plasma, and the following treatment was given:

Day of Illness	Total Glucose Solution (20–50 ml. at a time—every 3 to 4 hours)	Plasma
8th	100 ml. (60 ml. of 25% and 40 ml. of 50%)	2 pints (1.12 litres)
9th	220 ml. of 50%	2 " "
10th	220 ml. of 50%	2 " "
11th	190 ml. of 50%	2 " "

During the whole of the uraemic phase nothing was given by mouth and no intestinal lavage was attempted. Once the urinary flow was established the patient made an uneventful recovery, and apart from antimalarial therapy and haematinics no other treatment was given. Subsequent renal function tests were within normal limits.

On a physiological basis anuria can occur as a result of either one or more of the following factors: (a) renal circulatory failure; (b) renal excretory failure; and (c) renal secretory failure. I agree with Black and Stanbury that in lower-nephron-nephrosis anuria both the circulatory and the tubular factors enter into its pathogenesis. They wisely point out that in this type of anuria it is never possible to exclude the

possibility of spontaneous urinary flow, yet it would appear from my case that hypertonic glucose and plasma, either singly or together, did influence the establishment of the urinary flow at a very critical stage of illness, perhaps by affecting the renal circulation and nutrition and thus restoring its excretory and/or secretory function.

It is unscientific to draw any conclusions from one case, but as the combination of 50% glucose and plasma did appear to influence the course of the case at a very critical stage when other measures had failed I would recommend the above treatment in cases of anuria due to "renal anoxia" to elucidate its therapeutic value.—I am, etc.,

London, S.E.18.

S. KARANT.

Allergy, Rheumatic Fever, and Nephritis

SIR.—The excellent summary of recent experimental research reported in the leading article "Allergy, Rheumatic Fever, and Nephritis" (Jan. 1, p. 21) seemingly strengthens the allergic aetiological hypothesis. Clinical facts deny the restriction of the antigen to the haemolytic streptococcus or its products. Even the late Professor Lichtwitz,¹ who largely influenced the revival of the allergic hypothesis, denied this specificity in the initial sensitizing infection (the pathfinder), or in recurrent excitant infections (detonating), whether of the acute or chronic type (septic foci which vary in degree but not in kind). The relationship of the sera of rheumatic patients to streptococci is non-specific.² May I suggest that such has an analogue in the proteus-rickettsial relationship?

Too many exceptions destroy the validity of any theory which ought to arise out of and be suggested by the facts. While the current knowledge of the concept of allergy is in itself hazy, there are many dark places in this particular application: in bacterial allergy there is a definite period of sensitization; multiplicity of antigens (already noted) is not characteristic of induced allergy; while the clinical allergies may be a sequel to infections or are aggravated by mild infections, they disappear during acute infections.³ Rantz and his colleagues⁴ confirmed the original observation of Swift that even during the latent period between the clinical onset of rheumatic fever and the excitant infection the rheumatic process is at work, as shown by the E.C.G., E.S.R., and leucocyte count. I have noted that finger-tip tenderness, an invaluable sign of rheumatic infection,⁵ is present within a few hours of the onset of an excitant nasopharyngitis, itself resulting from contagion, so that the excitant mechanism, whether infectious or physical, such as chill, damp, or draughts, may be the same. Lichtwitz has argued that the almost instantaneous onset after physical excitants excluded the implication of micro-organisms. There is of course an analogue of epidemic coryza, a virus infection, and physical excitants.

As with the well-proven relationship of erythema nodosum or phlyctenular conjunctivitis to, say, tuberculosis, allergy would have been invoked, were the precise agent not known, to explain the coincidence of herpes simplex with excitant infections such as coryza, pneumococcal pneumonia, or malaria, with drugs such as organic arsenic, sulphonamides, or parenteral liver therapy, and with the normal alterations of the physiological cycle, as in recurrent menstrual herpes, which may be familial.⁶ All these phenomena have their analogues in the natural history of rheumatic diseases—the relationship to adventitious infection (acute or chronic, "septic focus" type), to drugs, or to physical excitants, the predominance of women of the child-bearing age in the incidence of rheumatoid arthritis, and the effects of puberty on the rheumatic infection of childhood.

A virus aetiological hypothesis is suggested by the facts, although against it is the view that the primary histopathological lesion is in the intercellular ground substance; but this seems a moot point.⁷ However, an allergic theory based solely on the haemolytic streptococcus is unsustainable.—I am, etc.,

A. D. McDWYER.

Exo-erythrocytic Forms of Malaria Parasite

SIR.—We fully appreciate the fundamental discovery of the pre-erythrocytic stage of the parasite of human malaria by Drs. H. E. Shortt and P. C. C. Garnham, Sir Gordon Covell, and Mr. P. G. Shute (*B.M.J.*, 1948, 1, 547). This discovery closes the gap between the anophelic cycle and the human

cycle of the parasite's life. Shortt and Garnham's recent findings (*B.M.J.*, 1948, 1, 192) of the persistence of an exo-erythrocytic cycle in *P. cynomolgi* even several months after the infection has started has strengthened the opinion, prevailing among malariologists for some years now, that persistence of the infection during the interval between the attacks of fever as well as the origin of relapses and the resistance to drugs in latent malaria are phenomena connected with the existence of exo-erythrocytic forms.

We cannot agree with the assumptions of this theory. We cannot accept the view that the perseverance of the infection is, as most observers believe, necessarily dependent upon the parallel persistence of plasmodial exo-erythrocytic forms. On the contrary, relapses are observed in individuals with latent malaria within an hour or two after strong emotion, shock, bomb explosion, cold baths, severe haemorrhage, surgical operations, etc., and this fact necessarily implies the existence of a developing endo-erythrocytic focus of parasites somewhere in the body of the individual. We are forced to assume that the endo-erythrocytic parasites have continued their focal life without ever passing into the general circulation.

Again, in individuals suffering from latent malaria, or rather focal malaria, a single injection of adrenaline intravenously is followed by the rapid emission into the peripheral circulation of endo-erythrocytic parasites in various stages of development. Such parasites are obviously originating from an endo-erythrocytic cycle and not from an exo-erythrocytic cycle. In the infection of fowls (*P. gallinaceum*) induced with infected blood a latent period follows the septicaemic phase, though sometimes this latent period is broken by minor relapses. In such hosts the exo-erythrocytic forms usually disappear towards the end of the second month. At the same time the infection is still active in the internal organs, particularly in the spleen and liver, with the presence of small numbers of endo-erythrocytic parasites and fresh granular pigment, probably originating locally, giving proof of the continuance of the schizogonic endo-erythrocytic cycle (D'Alessandro, Oddo, and Smiraglia).

In human *vivax* malaria induced by infected blood recurrences can occur, although less frequently as compared with infection with sporozoites. Analogously, according to Hawkins, Perry, and Thurston, a relapse may be provoked by splenectomy in monkeys with latent *P. cynomolgi* infection, but this occurs both when infection is induced by blood or by sporozoites.

Again, from the standpoint both of physiology and of pathology there is abundant evidence of the existence of a "focal" phase of the infection—that is, the existence of persistent moribund foci which maintain infection and disease long after the septicaemic phase has passed. Such foci, where endo-erythrocytic parasites can go on developing, are found in the splenic reservoirs of red blood corpuscles described by Barcroft and Binet, and are under the control of the spleno-contractile action of adrenaline. In the blood reservoirs, which are practically devoid of plasma, endo-erythrocytic parasites continue reproducing, protected by their position outside of the normal circulation from the action of antibodies and chemical substances. These facts explain the failure of attempts to eradicate the disease by means of chemical substances introduced into the circulation, because they never reach the parasites in the reservoirs of red blood corpuscles.

The above is only a short summary of the views expressed in my book, *Nuove Vedute sulla Malaria* (Rome, 1946), and by J. Radvan in *La Splenocontraction en Thérapeutique* (Bucharest, 1945).—I am, etc.,

Centro Sciliano di Malariologia, Palermo.

MAURIZIO ASCOLI.

Infective Ear Disease

SIR.—I am indebted to Mr. T. A. Clarke (Jan. 15, p. 111) for his criticism of the methods of treatment of chronic suppurative otitis media in factory employees. I am in agreement with the principles on which he bases his method of treatment for the simple type of tubal infection or tympanic sepsis—namely, prevention of stagnation of the discharge and the reduction of the bacterial flora by dehydration and antibiotics. The choice of method used in the investigation reported in my paper was dictated by its applicability to the conditions of the factory surgery and because the results from its use were already

known by otologists. The results obtained in the factory surgery could thus be compared with those obtained elsewhere. It is not considered that other treatments are less efficient, and an assessment of treatment methods was not attempted.

As stated in the paper, the object of this part of the investigation was to determine the value of the factory clinics in treating ear diseases in the associated population. It would be helpful if one could compare the results of treatment obtained in the factory investigation with those obtained by the method Mr. Clarke advocates, if only because the latter requires less time spent on treatment. Tables I and II (taken from my full report to the M.R.C.) will, I trust, supply the additional information Mr. Clarke asks for.

TABLE I.—*Chronic Suppurative Otitis Media According to Position of Perforation*

	"Recurrent" Cases			"Continual" Cases		
	Central	Marginal	Superior	Central	Marginal	Superior
No. of ears seen ..	122	0	12	128	22	30
Percentage distribution	134 = 42.6%			180 = 57.6%		
Percentage distribution	91%	—	9%	71%	12%	17%
Average age at onset of first attack	13	—	16	17	14	18
No. of ears treated ..	102	—	11	111	20	21
No. of ears cured ..	83	—	9	60	7	14
Percentage cured ..	82%	—	82%	54%	35%	52%
No. of ears quiescent	5	—	—	9	3	2
Percentage quiescent	5%	—	—	8%	15%	7%
No. of ears failed ..	—	—	—	6	4	6
Percentage failed ..	—	—	—	5%	20%	22%

Table I shows that out of 19 ears rendered quiescent by treatment 14 had central perforations and only two had attic perforations.

TABLE II.—*Chronic Suppurative Otitis Media—Effect of Granulation Tissue on Results of Treatment*

	"Recurrent"		"Continual"	
	With Granulations	Without Granulations	With Granulations	Without Granulations
No. of ears seen ..	26	108	64	116
No. of ears treated ..	23	89	53	105
No. of ears cured ..	16	76	23	58
Percentage cured ..	70%	85%	43%	55%
No. of ears quiescent	2	3	2	12
Percentage quiescent	9%	3%	4%	11%
No. of ears failed and % failed	—	—	8 = 15%	8 = 7%

Table II shows that four ears, with granulation tissue present at the start of treatment, became quiescent. The perforation was central in the membrana tensa in three, the granulations arising from the tympanic membrane or meatal wall, and marginal in one, the granulations arising from the tympanic annulus. Before daily treatment was discontinued and the ear classified as quiescent the granulations had become healed by epithelization for several weeks. No case of obvious cholesteatoma was classified as quiescent.

With the present shortage of hospital facilities some grading of the severity of the cases is essential. It is due neither to over-tolerance nor dilatory decision, but to hard necessity, that cases of minimal infection are regarded as less urgently in need of surgical intervention than cases with profuse otorrhoea persisting despite conservative treatment. To advise operation for every case of quiescent ear disease is not possible in all treatment centres. Furthermore, it is unnecessary. Out of six quiescent ears treated in this investigation two had become dry six to eighteen months later (Table X of report). These results are corroborated by the examination of any series of cases of soundly healed middle-ear disease. A few will be found to have suffered an extensive destruction of the ossicles or the tympanic annulus from osteitis. The infection has obviously been overcome by natural resistance, possibly aided by conservative treatment.

Nevertheless it is agreed that persistent activity in a quiescent ear should be given the respect it deserves, and surgical intervention, which may in some cases be on the lines advocated by Mr. Clarke, will eventually have to be considered.—I am, etc.,

Birmingham.

COLIN M. JOHNSTON.

SIR,—In his letter on infective ear disease (Jan. 15, p. 111) Mr. T. A. Clarke raises doubts as to whether regular daily treatment of chronic middle-ear suppuration is necessary. Also, in discussing Mr. Colin M. Johnston's advocacy (Dec. 18, 1948, p. 1049) of syringing the ear, he states that he knows "of no method more calculated to perpetuate infection: the easiest way to set up middle-ear discharge in a case with dry perforation is to syringe the ear."

No sensible person would syringe the ear with a dry perforation. The discussion surely centres round the treatment of active chronic middle-ear suppuration, and the subject is best approached by considering the fundamentals. Whatever method is used in treating the ear, so as to give the body's natural processes for overcoming the established infection the best chance of success it must be directed towards thorough cleansing of the ear to remove the usual foul discharge in which it lies bathed and to keep the ear as dry as possible. To achieve these ends we have the two principal schools, the advocates of the dry and the wet methods. The dry method consists essentially in thorough mopping of the ear, followed by removal of as much discharge as possible from the middle ear through the perforation by suction, then the insufflation of whatever powder the surgeon happens to favour. This form of treatment must of necessity be carried out by the otologist himself.

The wet method consists of thorough cleansing by washing out the ear with a drying agent; formaldehyde in the strength of 1 dr. (3.5 ml.) of 20% solution to a pint (568 ml.) of warm water has this effect. The meatus is then mopped dry. The latter method has the advantage that it can be carried out as a routine by a nurse with some training in ear work, and this is of immense practical importance in a large out-patient department. As regards the application of silver nitrate, this can be gratifyingly successful in cases where the granulations are purely superficial, but can have no lasting effect when they are indicative of deeper-seated bone disease.

To revert, then, to the question of frequency of treatment by either method, the rate of accumulation of discharge from a suppurating middle ear is usually such that any treatment applied less frequently than once daily must leave the ear bathed in pus for most of the time. If Mr. Clarke has been able to obtain good results from "treatment . . . perhaps once, perhaps repeated at weekly intervals three or four times," he must find the work of his out-patient department greatly relieved. My own experience has been disappointing in that I have not seen cases resolve under the dry method of treatment which had failed to do so after an adequate trial of the wet. In the light of the claims appearing from time to time for exceptional results from the dry method I have found on attendance at clinics where it is practised that there are as many cases of chronic suppuration attending as anywhere else. In addition, "free insufflation of powder largely filling the meatus," as Mr. Clarke describes, often leads to caking of the powder into a mass which may be hard to remove and must in some cases lead to damming up of discharge.

On the whole, then, I have found no advantage in results obtained by the dry method to offset the disadvantage that it requires the personal attention of the specialist, and that attention I hold to be necessary daily.—I am, etc.,

Glasgow

ALEX. R. HARPER

SIR,—Mr. T. A. Clarke (Jan. 15, p. 111) questions the truth of the statement made in your leading article (Dec. 18, 1948, p. 1068), "It seems certain that regular daily treatment is the best method of cleaning up infected ears," and then proceeds to a very curious defence of his own views. His first plea is that "the evidence must be considered," but this is immediately followed by the dogmatic and unsupported statement that he knows of no method—referring to daily syringing or dry mopping and drops—more calculated to perpetuate infection.

This seems a very extravagant answer to the work of Banham,¹ who by the method of daily dry cleaning and light dusting with 2% iodine in boric acid powder obtained a dry ear in 82.5% of 200 cases of chronic suppurative otitis media occurring in R.A.F. personnel; and to the work of Mr. Colin M. Johnston (Dec. 18, 1948, p. 1049), who obtained 81.2% dry ears in a series of 316 cases by daily

syringing followed by spirit drops or a simple powder. Perpetuation in these cases was remarkable by its absence, and so far it would appear that the only evidence open to scientific consideration has been produced in support of the daily cleansing method.

Mr. Clarke submits that a result as good could have been obtained with far less treatment, but, whether or not figures are available in support of his contention, legitimate criticism can still be levelled at the treatment he advocates. First, if it is agreed that it is desirable to be able to assess the progress of treatment not only by the volume of the discharge from the meatus but by comparative inspections of the anatomy of the tympanic membrane and cavity, then it must be said that silver salts are most unsuitable local applications, as they discolour the whole picture and make qualitative observations very difficult if not impossible.

Secondly, Mr. Clarke states that his treatment (very careful toilet of the meatus, application of 20% silver nitrate, and the filling of the meatus with pulv. P.S.U.—sulphathiazole 10 parts, urea 1 part, penicillin 2,000 units per gramme—at weekly intervals), applied "perhaps once," will yield results equal to those obtained by Johnston. What one would like to know is whether criterion of cure is based on the middle ear being found dry after a dredging operation to remove all the powder, or on the fact that the powder has remained *in situ* and not been washed away by discharge. If the first is the case, how often does a syringe have to be employed to get the middle ear clean? And if the second, how long is the powder allowed to remain, with its obvious disadvantages of completely preventing subsequent inspection of the middle ear and of interfering with the hearing?

Thirdly, he states that such treatment—i.e., filling the meatus with sulphathiazole and penicillin powder—is only with extreme rarity followed by skin reactions. To which one would ask, General or local reaction? Because it is not uncommon in hospital practice to find patients with a desquamating otitis externa, generally involving the drum, who have had penicillin in their meatus, either in drops or in a powder, prior to their visit.

Finally, to provide more of the evidence which Mr. Clarke regards as so essential before daily cleansing routines are adopted, results are given of treatment in the first hundred consecutive cases treated in the chronic ear clinic of St. Thomas's Hospital during 1948. The treatment consisted of meticulous dry mopping after suction of the middle ear with a Siegle's speculum, followed by light insufflation with 2% iodine in boric acid powder. The treatment was carried out daily wherever possible, a minimum of four attendances a week being the rule. The criterion of immediate cure was an absolutely dry middle ear. The results were as follows:

Number of patients treated	100
Number of immediate cures	73
Average length of treatment	12.4 days

Cases are not treated for long periods. Two weeks' adequate conservative treatment will suffice in the great majority of cases to make an accurate diagnosis, to cure those cases capable of cure by conservative treatment, and to convince the patient that all reasonable non-operative measures have been given a trial before operation is advised. Thus all cases referred for conservative treatment are reviewed at the end of two weeks' treatment, and in only a very small number is further conservative treatment advised.

I have to thank the staff of the E.N.T. Department of St. Thomas's Hospital for their permission to use the figures from that hospital

—I am, etc.,
London, S.E.1.

S. R. MAWSON.

J. Laryng., 1944, 59, 117.

SIR,—The able letter from Mr. T. A. Clarke on this subject (Jan. 15, p. 111) raises points of the utmost importance to all otologists. Several papers read at the Royal Society of Medicine by Service members after the war gave remarkably good results from daily treatment of chronic otorrhoea. No doubt the treatment was carried out under the watchful eye of the otologist and not left to half-trained assistants. The conclusion is, I think, that daily treatment is a sound method of treatment

only if efficiently carried out. As Mr. Clarke says, indiscriminate syringing is a positive danger.

It is a curious thing that treatment by zinc ionization is hardly ever done or even mentioned in aural departments. Conceived by Professor Leduc, of Nantes, and introduced to this country by Mr. Friel, zinc ionization is to my mind the greatest advance in the treatment of chronic otorrhoea during the past twenty-five years. Of course it is limited to certain cases. Ionization of an "attic" suppurative with a pinhole perforation is simply waste of time, but where there is an adequate perforation enabling the middle ear to be washed out with an attic cannula the results are often dramatic. The "toilet" of the ear and the ionization of course have to be done very thoroughly by the otologist and not just left to the electrotherapy department. Many cases, even those of many years' duration, clear up with one ionization. The saving of time in these cases is obvious. The neglect of this method of treatment is to be deplored and has been a matter of much regret to me. It is carried out with success in the L.C.C. clinics.—I am, etc.,

Guildford.

T. B. JOHNSON.

Treatment of Simple Ganglion

SIR,—It is most interesting to hear that Mr. G. H. Colt (Jan. 15, p. 113) and Mr. J. H. Kirkham (Jan. 15, p. 113) find, as I do, that the best treatment of a simple ganglion is simple pressure. I should like to thank Mr. John Hosford (Jan. 15, p. 112) for his kindly criticism of my letter (Jan. 1, p. 32), but I do not "rupture" the ganglion by pressure, but replace the jelly into the tendon sheath. On many occasions I have actually demonstrated to onlookers the jelly passing into the tendon sheath, and then moved the jelly about in the sheath.

I have, of course, followed up my cases and have found that the great majority do not recur. I am sorry Mr. Hosford has not had quite such good luck, and suggest as a reason that I probably see more "acute" or "traumatic" ones. One not infrequently sees them within a day or two of their occurring, and often within a week or two, and I think we shall agree that recent cases are more easily cured by pressure than old-standing ones in which the jelly has become harder.

I am aware that the modern teaching in the textbooks is that the majority of ganglia arise from joints, but I am afraid that I do not believe this. Mr. Hosford says in his letter that "the ganglion will be seen to arise from the capsule of a joint." Does he believe that a ganglion is formed by "mucoid" degeneration of the capsule of the joint or of a fibroma of the capsule? In the older textbooks it used to be taught that a ganglion was formed by mucoid degeneration of a tumour of a tendon sheath. I have never believed this, for I have seen hundreds of ganglia, but I have never seen one of these hypothetical tumours before degeneration has occurred.

The theory that a ganglion arises from the capsule of a joint is rather difficult to believe. Does a ganglion actually arise from the synovial membrane of a joint? One has seen many cysts containing synovial fluid arising from joints and many cysts containing jelly arising from tendon sheaths, but never has one seen cysts containing jelly arising from joints or cysts containing synovial fluid arising from tendon sheaths.

It is well known that small pockets and projections of the tendon sheath occur in some cases, which require some skill and patience in dissection, but has anyone ever proved that these pockets actually are continuous with the synovial membrane of the joint? Has anyone put a probe into the joint before the scalpel has got anywhere near? Has anyone demonstrated by the injection of a radio-opaque fluid that a ganglion does communicate with a joint? To-day a skilled orthopaedic colleague kindly allowed me to be present when he was dissecting out a ganglion over the wrist. At first sight it did appear as if there was a small hole in the base of the ganglion, but no probe could be passed into the joint and we agreed that in this particular case no communication existed.

We will all agree that many ganglia arise from tendon sheaths and have no connexion with joints—e.g., the pea-like bodies so commonly seen on palmar tendons. I have never seen a direct connexion between a ganglion and a joint, but I am willing to be convinced if someone will open up a ganglion and demonstrate a probe passing into the joint before the capsule of the joint is dissected. My opinion is that the textbooks are wrong: that the great majority of, if not all, ganglia are

pressure was applied over the shoulder in an effort to push the arm forward within reach. When hope had almost been given up, the shoulder flopped forward with a snap, and then the arm was drawn down with difficulty. The head was then delivered by suprapubic pressure and a very gently applied Mauriceau-Smellie-Veit grip. The baby, though badly shocked, revived after a few minutes following the administration of lobeline and O_2/CO_2 mixture. Subsequent x-ray examination of the child's shoulder showed a fracture about the middle of the clavicle, which fortunately united satisfactorily.

Questioning the patient afterwards revealed that since the birth of her last child some ten years previously a simple colporrhaphy had been performed for prolapse, and when this failed to cure the condition a Fothergill operation with radical amputation of the cervix had then been done. Unfortunately, and for obvious reasons, this history was not obtained before delivery. Examination on the tenth day showed almost complete absence of the vaginal portion of the cervix, it being replaced by a small hole on the anterior wall of a rather narrow vault.

I hope that this will serve to show how easily one can be caught out by this unpleasant complication and to warn against too hasty amputation of the cervix in women of childbearing age.—I am, etc.

Acharacle, Argyll.

ROBERT S. C. FERGUSON.

Cervical Stenosis after Forceps Delivery

SIR.—Mr. Walter Calvert's memorandum on dystocia after amputation of the cervix (Jan. 8, p. 58) interested me because I have recently dealt with a similar case following previous forceps delivery.

The patient was aged 41 and had had three labours, the last of which ended in forceps extraction six years previously. Each of the babies weighed between seven and eight pounds. When seen by me in April, 1948, the patient was twenty weeks pregnant, and routine examination disclosed gross scarring of the upper vagina, the cervix being unrecognizable. There had been threats of abortion at the 12th and 15th weeks. It was hoped that this scar tissue would relax at labour, but she was booked to have her confinement in King Edward VII Hospital, Windsor, the possibility of delivery by caesarean section having been considered. Spontaneous labour started at term on Sept. 3, and when I was called I found her to be bearing down strongly and what at first appeared to be the foetal head distending the perineum. On closer examination this was found to be the thinned lower uterine segment covering the head, and no os was visible or palpable.

Lower-segment caesarean section was at once performed and a living child extracted. Again no suggestion of a cervical canal could be identified from above, but since she had menstruated, conceived, and had had two threats of abortion during the pregnancy was decided to wait and see whether lochia could be passed. On Sept. 7, three and a half days after operation, the patient had passed no lochia at all, and the centre of the lower uterine segment was therefore incised and a catheter stitched in. About 2 oz. (57 ml.) of thin, non-offensive, blood-stained fluid issued from the uterus. On Oct. 25 the patient attended the post-natal clinic. There was slight blood-stained discharge from the uterus, the latter being of normal size, and per speculum a very small aperture was seen at the upper end of the vagina.

It would appear that the previous forceps delivery had resulted in severe laceration, if not avulsion of the cervix, with resultant stenosis.

Windsor, Berks.

F. H. FINLAISON.

Neonatal Asphyxia

SIR.—Dr. W. N. Leak (Dec. 18, 1948, p. 1079) remarks, "I would only add that experience with caesarean babies is not quite applicable to normal births. For some reason caesarean babies are much more liable than others to die rather quickly and inexplicably."

My experience in general practice has also been that babies born from caesarean section do not breathe as spontaneously or as quickly as those delivered through the birth canal, and, furthermore, I believe that caesarean sections performed on patients in labour produce better-breathing infants than those cases where the operation is performed before labour has set in. These phenomena can be satisfactorily explained if we accept the actuality of foetal respiratory movements. Evidence to this effect has come from three sources: clinical observation, the presence of the contents of amniotic fluid in the lungs of infants at necropsy, and the presence of amniotic fluid itself in foetal lungs as demonstrated by the injection of contrast materials into the amniotic sac.¹

An experiment performed by myself last year confirmed Davis and Potter's observations. The possibility that anaesthesia and/or operative interference may account for the presence of contrast material in the lungs was completely eliminated in my experiment by the demonstration of its presence in the lungs of the intact foetus before hysterotomy. If, therefore, we accept the aspiration of amniotic contents by the foetus as a fact, we may account for the above phenomena of the caesarean baby. Two theories, a chemical and a mechanical one, suggest themselves to the writer. During the normal process of labour the placental circulation is disturbed, with a resultant condition of asphyxia, which sensitizes the foetal respiratory centre and prepares it for the onset of extrauterine respiration. Secondly, the process of labour, by squeezing the liquor amnii out of the foetal lung, prepares it for the extrauterine substitution of air for fluid.

The caesarean baby is denied both these beneficial effects of normal labour. Its lungs at delivery are still full, or partially full, of fluid, and its respiratory centre has not been sensitized: very often this infant is truly "drowned," and unless adequate measures are promptly taken it will succumb—hence the comparatively high death rate and incidence of respiration pneumonia in infants delivered by caesarean section.

The lesson then is that in all caesarean sections it should be a routine procedure to do intratracheal catheterization as soon as the infant is delivered.—I am, etc.,

Benoni, South Africa.

Classical Caesarean Section

SIR.—I would like to confirm the opinion expressed by Mr. Percy Malpas (Jan. 22, p. 156) that the lower-segment operation cannot always replace the classical operation.

Recently I had two similar cases, when the classical operation was a blessing and not an abomination. Both were elderly primigravidae, and each had a fibroid (the size of a foetal head) in the anterior wall of the lower segment. To do a lower-segment operation in these cases would have necessitated cutting through the fibroid. Such a procedure would undoubtedly have increased the risk of operative haemorrhage, post-partum infection, pulmonary embolus, etc. I was very glad to be able to turn around and do a classical section with no difficulty and much less risk.

Sheffield.

TIM BOLAND

Death at Birth

SIR.—The annotation entitled "Death at Birth" (Jan. 8, p. 64) stresses the need for more accurate information and certification of the causes of neonatal death. It seems important to draw attention to the fact that practitioners are often discouraged from the scientific approach to the problem and use of terminology taught them as students because of the legal problems involved.

In the terminology of the Medical Research Council's classification of disease, two of the most frequent causes of neonatal death are (751) intracranial injury at birth, and (753) asphyxia during or after birth, yet if either of these is stated on a death certificate it is refused by the local registrar of deaths and an inquest frequently ordered by the coroner. In my experience several scientifically minded practitioners and resident medical officers have performed post mortems on infants born under normal conditions in maternity homes, and, on certifying the cause of death as intracranial haemorrhage due to tentorial tear or other type of trauma, have found themselves in the coroner's court. They can hardly be blamed if on future occasions, in order to save parents further distress or themselves frequent attendance in the court, they retreat willingly to the vague but safer use of the terms "atelectasis" or "prematurity."

In this country many large teaching maternity departments can produce annual statistics compiled by their obstetric and paediatric registrars in which an attempt is made to state an accurate diagnosis. There is often a marked discrepancy between these statistics for neonatal deaths and those given in the annual reports of the medical officer of health for the particular area involved, particularly as regards the use of the term "prematurity" as a primary cause of death.

If any encouragement is to be given to greater accuracy of certification or the more frequent performance of post-mortem examinations on the newly born, it is essential that these legal difficulties should be overcome as soon as possible.—I am, etc.,

Millilitres Correct

SIR,—Dr. J. M. Hamill (Jan. 8, p. 72) revives and reinforces suggestions that have been put forward and made official in more than one edition of the *British Pharmacopoeia*. The B.P. 1932 suggested, too, the use of the word "mil" as a short designation for millilitre. That these suggestions have met with little response among those who use and make drugs indicates the strength of habit and shows how few read and act upon the recommendations made in succeeding prefaces to the B.P.

Thinking, perhaps, to get round it in another way, the B.P. 1948 has discarded the word mil and adopted the abbreviation ml. for millilitre. This seems rather a pity and somewhat defeatist, for mil is a good word and can be both an abbreviation and a word in its own right. Mil is short, to the point, indicative of the word from which it springs, and, printed or spoken, not to be confused with any other measure (which is more than can be said for millilitre). From a typographical point of view, the abbreviation ml. is undesirable, for it will often intrude an ugly and distracting point into running matter without saving type-space and, by encouraging the spoken use of millilitre, will invite typists and compositors to spell the word in full rather than use the abbreviation where that has been intended by the author or editor.

May I put in a plea for "mil," and hope that the next edition of the B.P. will revert to its use, having noted that since 1949 physicians, manufacturers, and pharmacists have come to adopt it?—I am, etc.,

Liverpool.

N. A. HERDMAN.

The End of Compulsory Vaccination

SIR,—The end of "compulsory" vaccination as of July 5, 1948, marked a red-letter day in England singularly well timed in its proximity to July 4 and to the bi-centennial birth date of Edward Jenner, who was born on May 17, 1749. This end to compulsory vaccination in England has intensified my desire to contribute a letter to the *British Medical Journal* as further suggestion for more careful discrimination in the process of vaccination.

Professor Major Greenwood (July 3, 1948, p. 23) has shown how the zeal of propagandism may overcome scientific facts, an example of which has recently been demonstrated in New York, where only twelve cases of smallpox were reported in a population of 5,000,000 people vaccinated within two weeks of the appearance of the first case. Coincidentally there were approximately 2,500,000 people daily in the city who must not have been vaccinated and in which group no case of smallpox developed. (It is estimated that the daily population of New York City is 7,500,000.) The incidence, therefore, of smallpox was much lower in the non-vaccinated group than in the vaccinated group. It is of interest to note that in the twelve reported cases of smallpox ten were convalescing from some acute infectious disease and an eleventh patient was pregnant. Experimental studies have shown that "where an animal is recovering from an acute stage of a disease, the absorption of an additional amount of antigen introduced through further injection may precipitate a new state of the disease and be responsible for aggravations."

At this most opportune time I would like to make a few random observations to promote some thought upon vaccination. In the outbreak of smallpox in New York City it has been stated that many people who became ill with one of a variety of illnesses several days after they were vaccinated called the health department to find out if the vaccination was responsible. Since in New York City there are 1,000 people ill daily, and since practically everyone in New York City was vaccinated, it was inevitable that some of these people would become ill and die. Vaccination does not stop the normal course of events, and vaccination should not be blamed for cerebral deaths, haemorrhages, etc.

These claims or "discredits" can best be answered by quoting Hans Zinzer, who states, "It is advisable to examine the reports of cases observed during epidemics, when doctors are expecting them and are more likely to scrutinize all obscure conditions with the disease in mind." Hans Zinzer was neither heard nor remembered in New York City because his admonitions were drowned out by worthless statistics and medical tradition, whereas efforts were made to excuse post-vaccinal reactions on the basis of people dying daily in New York City of normal causes.

I wish, therefore, to offer one single suggestion upon this red-letter day—namely, that we do not vaccinate when there is present a possible acute infectious disease. As you may have already surmised, the media of your distant channels has caused much more native littoral reverberation than have my own local efforts, and it is for this reason that I am desirous of writing to your *Journal*.—I am, etc.,

Newark, New Jersey.

EMANUEL ROSEN.

A Clinic under the N.H.S.

SIR,—Those of your readers who are interested in the development of the new Health Service may find food for thought in the following example of how it affects clinic work. The *I.S.T.D. (Institute for the Scientific Treatment of Delinquency)* was established 16 years ago as a unique experiment. It was supported by voluntary contributions and the directors and the medical staff gave their time free. Although handicapped by lack of money and staff, it nevertheless succeeded in treating a considerable number of patients, carrying out scientific research, arranging lecture courses, and so established an international reputation for this pioneer work.

The psychiatric treatment of criminals and psychopaths is as yet in its infancy. Patients whose main trouble is their inability to fit in with accepted social codes are not likely to fit in with accepted methods of psychotherapy, to attend regularly, to tell the truth, and to co-operate. Convinced that if a patient is unable to fit himself to a therapy the therapy must fit itself to the patient, I have worked out a method of seeing these criminal patients at my private consulting-room whenever they find themselves in an emergency, helping them in their practical difficulties, giving them if necessary food or money, establishing personal contact, and doing psychotherapy whenever the patient is ready for it. With this very unconventional method I find it is possible to get results in a number of otherwise intractable cases.

The old I.S.T.D. gave me every latitude and encouragement to experiment. Since July 5, however, its clinic has been nationalized, and I have been informed that all treatment must be carried out on the premises of the clinic in my allotted time; also that not only would I not be paid for the time I spent with my old I.S.T.D. patients if I continued to see them in private because they could not attend in clinic time, but that they would be struck off the clinic list. On the other hand I would be paid only for the time actually spent in the clinic building, even though, most of the time, there were not enough patients to keep me busy. The Government, so I was informed, is paying us for time, not for skill, and as far as I know I was the only psychiatrist who objected to getting paid for sitting unoccupied in the clinic premises.

As I had been intimately connected with the I.S.T.D. for 16 years I tried to accommodate myself to what I regarded as a stupid situation made worse by the attitude of the clerical staff, who soon developed the Civil Service manner. But when the appointment clerk refused to allow me to see three more patients in my allotted time, informing me that it was she who fixed my appointments and decided whom I was going to see and for how long, I had no alternative to immediate resignation.

Already the Ministry has spent money freely on salaries and clerical assistance and is likely to spend more in the near future. The clinic is likely to get a bigger and up-to-date building, a larger medical and a still larger clerical staff. No doubt the Government will soon have a "showplace" run with "efficiency"; the doctors who are accommodating enough to fit in will get easy money and easy work; patients who are not too ill to fit in will get treatment. Nevertheless, the scientific standing of the clinic will decline, both because there is no scope for elasticity and research and because conditions are not likely to attract the best doctors.

Obituary

R. L. DODDS, M.Ch., F.R.C.S., F.R.C.O.G.

Mr. Robert Leslie Dodds died suddenly on Jan. 26 at the early age of 50. He was born in Dundee in 1898, the son of the Rev. R. W. Dodds, and received his education in Belfast, first at the Methodist College and later at Queen's University. He graduated with honours in 1920, and after holding various appointments, including that of demonstrator in anatomy, proceeded to take the F.R.C.S. in 1927 and the M.Ch. of his own university in the same year. Further resident experience followed in London, this time confined to the specialty he had chosen, and very soon he was appointed to the staff of the City of London Maternity Hospital, the Samaritan Hospital, and the French Hospital. Here Dodds was given scope to develop those abilities which had been evident early in his career. He rapidly reached the front rank as a skilful operator, and his advice on obstetric problems was widely sought.

When the London County Council took over the old Guardians' hospitals in 1934 Dodds was asked to help in the reorganization of their maternity services. Their present efficiency is largely a result of the work he did at that time and which he continued subsequently as consultant at St. James's Hospital. He was in addition obstetric consultant to the Ilford and Edmonton borough councils and to the Bearsted Memorial Hospital.

He had served in the 1914-18 war as a surgeon lieutenant in the R.N.V.R., and was on active service in destroyers. During the recent war he was a major in the R.A.M.C. for 18 months, being employed appropriately enough as surgeon to a troopship for part of that time. Towards the end of 1944 he had to relinquish his commission on the grounds of ill health.

Dodds had a natural charm which endeared him to all with whom he associated and combined with his innate modesty to make association with him a delight. His many friends and patients will mourn his passing and extend their sympathy to his widow, who assisted him so devotedly during his long illness.

Mr. R. Christie Brown writes: Leslie Dodds was my friend for 20 years and was one of the kindest and most generous of men. I have known few people who had his ability to endear themselves to so many. His most attractive quality was his humanity, and this, coupled with a wisdom which few possess, made him one of the best friends a man could have. His sense of humour and Irish wit were irresistible and also served his colleagues in very good stead, particularly in committee work. I have known many difficult situations saved by his ready wit. He was a universal donor, and in the days before blood banks this, and the fact that one could always count on his help in an emergency, must have cost him a lot physically. I recall two outstanding occasions on which Dodds came to my help by giving his blood to my patients, one of whom was the wife of a colleague whom I visited with Dodds. She was so ill with a ruptured ectopic gestation that we operated upon her in her own home. Dodds not only assisted me with the operation but gave the patient a transfusion of his own blood. I was a young man then, comparatively unaccustomed to dealing with such critical situations, and I have always felt grateful to him for the help so freely and unostentatiously given. The tragedy of his premature and sudden death is to me heightened by the feeling that we have lost not only a good friend and colleague but also someone who had the qualities of the humanitarian, with a regard for people as individuals, understanding and charity for their weaknesses, and tolerance for even the arrogant and the stupid. In the present state of the world such qualities tend to be at a discount, and the loss of any one of their champions is indeed tragic, but particularly so when the loss is also that of a personal friend.

W. E. FOGGIE, D.S.O., M.D., F.R.C.P.Ed.

Dr. William Edward Foggie, who died in Dundee on Jan. 13 at the age of 79, had been closely associated with the Dundee Royal Infirmary for fifty years. He was born in Dundee, and as a boy attended the High School there. On leaving school he went to Edinburgh University and entered the Faculty of Arts, taking the M.A. in 1889. Thereafter he studied medicine and graduated M.B., C.M. in 1893. He was then one of the only two resident medical officers in Dundee Royal Infirmary for a time. He settled in practice in his native town, and in 1899 was appointed to the staff of the Infirmary as assistant physician. In 1907 Dr. Foggie was promoted visiting physician for diseases of the skin, and held this appointment for twelve years, which included, however, a long absence on military service. When he came back from France he returned to the medical side of the Infirmary, and from 1922 till 1932, the year of his retirement, he was senior visiting physician. Dr. Foggie continued to act as physician to the Royal Victoria Hospital and the Sidlaw Sanatorium. He was also for many years a teaching member of the staff of St. Andrews University, holding a lectureship first in dermatology and afterwards in clinical medicine.

In the 1914-18 war Dr. Foggie served with distinction. He was mobilized as a Territorial in 1914, and in 1915 went to France in command of the 3rd Highland Field Ambulance in the 51st (Highland) Division. He served throughout in France and Belgium till demobilization in 1919. In 1918, when he held the rank of lieutenant-colonel, he was awarded the D.S.O. He became a member of the Royal College of Physicians of Edinburgh in 1922, and in 1926 was elected to the fellowship. He will be remembered by an older generation as a member of the Association of Physicians, on the executive of which he served for three years. He had been a member of the B.M.A. since 1894, and was president of the Dundee Branch in 1933-4. His health began to fail gradually over a year ago, but he was able to get about until some two months before his death.

Dr. Foggie was held in high regard by his colleagues for his clinical acumen, wise counsel, and unfailing good humour. He was an excellent teacher of medical students, who recognized in him a good physician and a good friend.

Dr. PHILIP HEWER WELLS died at the age of 56 on Jan. 17 at Stratford-on-Avon after a long illness. The third son of Arthur Lethbridge Wells, who was senior surgeon to the Central London Ophthalmic Hospital, he was related on his mother's side to a long line of medical men, several of whom were intimately connected with St. Bartholomew's Hospital. Dr. Wells qualified there in 1915. He was awarded the Brackenbury Scholarship, the Kirkes Scholarship and Medal, and the Willett Medal, and he was elected president of the Abernethian Society. After acting as house-physician to Lord Horder he joined the R.A.M.C. and was appointed medical officer to the 2nd Battalion Coldstream Guards, a regiment of which he remained immensely proud. Within eighteen months he was awarded the M.C. and bar, and later served a short period in Russia. Returning to civil life he acted as house-physician at the Radcliffe Infirmary, took the M.R.C.P., and went into general practice with his uncle, Mr. Earnshaw Hewer, F.R.C.S., in Stratford-on-Avon. Here he spent the whole of his working life. On the outbreak of war in 1939 he was appointed as medical specialist to the 10th British General Hospital and went to France. After the evacuation he held a number of appointments until in 1943, while acting as consulting physician to the South-Eastern Command, his health broke down and he was later invalided out with the rank of lieutenant-colonel. On his return to Stratford-on-Avon, with great courage he continued to work as long as this was physically possible. Dr. Wells was a man of great physical strength, a fine athlete, and an excellent player of ball games, in which he delighted. But with all his qualifications he will be best remembered for his forceful personality, his spontaneous generosity, and his uncompromising defence of what he considered to be the right. He leaves a widow, two sons, and two daughters.

H.G. writes: Now that Philip Wells has left us, it seems fitting to recall the great man with whom I worked rather than the shadow of his former self that his illness had made him during the last year of his life. I was privileged to become his junior partner nearly twenty years ago, and soon learned to realize his outstanding personality and the magnificent mental and physical capacities with which he had been endowed. He

had the highest integrity and expected the same standards from his colleagues and from all with whom he came in contact. Like all strong men, he had that capacity for gentleness which showed itself during his rare excursions into surgery, but mostly in his dealing with children, who all loved him, and whose care was his especial pleasure. Among many recollections are his guidance and encouragement in difficult midwifery; the effortless accuracy of his mashie shots; the terrific force of his first service; and the roars of laughter which his mimicry evoked. When he left in 1939 to rejoin the Army there was something missing from among us which, alas, never returned in full, as he was a sick man when we saw him again. What we missed the Army gained. Many of those who served with him have spoken of him with great affection and will, I know, share our sense of loss. His life was all too short, but his memory will gladden the hearts of many of us for as long as we live.

Dr. GRAHAME RIGBY RAWLINGS, who died on Nov. 23, 1948, at the age of 37, was anaesthetist to the Dorset County Hospital. He took his Conjoint qualification in 1935, graduated M.B., B.Chir. at Cambridge, and took the D.A. in 1937. He was casualty officer and house-physician at St. Thomas's Hospital, and then became senior resident anaesthetist there. In 1938 he went to Calcutta, where he was an anaesthetist on the honorary staff of the Presidency General Hospital. During his years in India he was an energetic and successful practitioner of anaesthesia and of general medicine, and was soon acknowledged as one of the leading anaesthetists in the country. He had a fertile and inventive mind and great mechanical ingenuity, and did much work on the development of apparatus and appliances. He left India in 1948 to devote his full time to anaesthesia in this country. His early death is a great loss to the profession.—R. F. W.

Dr. EDWARD KEITH MULINDER died in New Zealand on Dec. 9, 1948, at the age of 40. Dr. Mulinder was born in New Zealand, and was educated there, graduating M.B., Ch.B. in 1933. He came to England in 1935 for further study and experience. From 1936 onwards he was employed in L.C.C. mental hospitals at Friern and Tooting Bec. He had taken the D.P.M. in 1938, and he joined the R.A.M.C. as a specialist, serving as area psychiatrist in various parts of England. On the opening of the Second Front, Major Mulinder went to Normandy with the advanced section of the 32nd British Psychiatric Hospital which landed on D+18. Following the battles of Caen and the Falaise Gap he wrote an article which was published in this *Journal*. Mulinder served in psychiatric hospitals in N.W. Europe till after the end of the war and, on returning to England, at Banstead Hospital, Surrey. He was demobilized in 1946 and returned to New Zealand to take up an appointment in the Mental Hospitals Department. Until recently Dr. Mulinder was medical officer at Kingseat Hospital, Papakura, where he was held in high esteem by both the staff and the patients. His early death is a great loss to the profession. Dr. Mulinder is survived by his widow and four young daughters, all of whom were born in England.

Dr. WILLIAM JOHN YOUNG, who died on Dec. 28, 1948, at the age of 79, was one of the best-known practitioners in Cambridgeshire. He qualified first as a chemist after serving an apprenticeship, and then took the L.R.C.P., M.R.C.S. in 1900 after studying medicine at Liverpool University. As a student Young won the Torr Gold Medal and the Senior Lyones Scholarship for Anatomy. He became a demonstrator at the new medical school, and he also assisted Professor A. M. Atkinson in preparing the dissections for the illustration of Cunningham's *Textbook of Anatomy*. He settled at Harston, Cambridgeshire, soon after qualifying, and he remained in practice there until 1945. A man of great energy of mind and body, in the early days he found horses too slow and took to the bicycle, often covering over thirty miles a day. Because of the bad roads, Young was often to be seen in winter riding across field paths and side-walks. Outspoken, a hater of humbug, yet tender in the presence of great trouble, he endeared himself to his patients, and he never refused an emergency call. Midwifery was one of Young's special interests. He safely delivered over 2,000 babies and counted it a blessing that he never lost a mother in labour. In the 1914-18 war Young was visiting patients as early as 7.30 a.m., and at 10 a.m. he began a day's work presiding over medical boards, returning home in time to pay evening visits and conduct his surgery. Always an enthusiastic member of the local medical society, he was frequently heard reading papers or in discussions. He represented the Cambridge and Huntingdon Branch at the annual meeting held at Aberdeen in 1914 and at three London meetings. He was honorary secretary of the Division in 1924-5 and president in

1927-8. Dr. Young's recreations included village cricket, tennis, swimming, reading, and he was particularly interested in French and in the Greek classics. For over fifty years he read daily a part of the Bible, and he imposed upon himself a rigid self-discipline. The esteem of all his friends was demonstrated on the occasion of his seventy-fifth birthday and his official retirement. A presentation was made to him by over 1,000 friends and patients from the twenty-two villages he served. His own words seem a fitting conclusion: "In my wildest dreams I never thought of anything of this kind. During my forty-four years here I have made some attempt to live up to the high traditions of medical service and follow them as far as I could. To find myself in these circumstances is rather an overwhelming triumph." His life was a triumph—he loved his profession and no one asked his help in vain. His gentle nature and indomitable spirit made him a living example to others.—C. W.

Dr. WILLIAM HENRY PASSMORE died on Dec. 31, at the age of 76, in Carshalton, where he had practised for over forty-five years. Passmore had been a man of great energy, with many activities outside his general practice. His surgical ability was great, and was recognized by his fellow practitioners over a wide area. He was a general-practitioner surgeon of the best type, knowing his limitations, but an expert in dealing with abdominal emergencies and with fractures. Under his influence the Carshalton War Memorial Hospital, to which he gave so many years of voluntary service, had a deservedly high reputation. In his younger days he had passed the primary examination for the F.R.C.S. and had been prosecutor at the College, and with a natural surgical aptitude he developed a fine technique. He had been resident obstetric officer at Charing Cross Hospital, where he qualified in 1899, and retained his interest in midwifery. His acknowledged skill in this subject led to his appointment as consulting gynaecologist to the Carshalton U.D.C. In the 1914-18 war his energy was such that he became surgeon to the two large Red Cross hospitals at Morden Hall and Morden Grange at a time when his young partner had left for service in France. Passmore managed it all by doing two hours' work at the hospitals before breakfast. In 1919 he was one of the founders of the Sutton and District Medical Society, which has continued with great success, and he was its first treasurer. It was mainly due to Passmore's energy in raising money that the War Memorial Hospital, Carshalton, was opened and finished completely free of debt. Passmore was to many of his patients not merely a doctor but one who became their wise counsellor and a lifelong friend. Those who knew him well will, above all, think of him as a lovable personality who gave his energies to the benefit of his neighbours, and will ever hold him in their memories with affection. He is survived by his widow, who was of exceptional help to him in his professional work, and by his son and daughter.—T. H. W.

Dr. ALBERT ERNEST HODGSON died at his home in Maghull, near Liverpool, on Jan. 2 at the age of 68. Apart from the interruptions of two world wars the whole of his professional life was spent in the treatment of infectious disease. Dr. Hodgson was born in Redcar. His medical education was at Cambridge and Edinburgh, and he graduated M.B., Ch.B. in 1903. In 1911 he proceeded M.D., and was commended for his thesis on the treatment of diphtheria. He took his D.P.H. at Cambridge in 1906, and in that year was appointed R.M.O. at the City Hospital East (Mill Lane), Liverpool, where he had his first extensive experience of diphtheria and other infectious diseases. This period was broken by his specialist service in the R.A.M.C. from 1914-19 in India and at Salonika and Malta. On his return to England he was appointed officer in charge of the North-West Area bacteriological laboratory and cerebro-spinal centre at Kinnel Park. It was here that he met his wife-to-be, Norah Lelean, sister of Professor Lelean, who held an administrative nursing post there. This was an ideal marriage, though there were no children. His wife's death, about ten years ago after a period of illness, was a very great blow to Dr. Hodgson. In March, 1919, he was appointed principal medical officer at Fazakerley Hospital, Liverpool, serving under Claude Rundle, whose methods of bed-isolation and cubicle nursing he eagerly followed. At this time Rundle and he drew attention to the need for larger doses of antitoxin owing to increased gravity of diphtheria, which ten years later were shown to be due to particular strains of the diphtheria bacillus. In 1934 Hodgson succeeded Rundle as medical superintendent. He was keenly interested in the treatment of anthrax, in which he had great success, having a consecutive series of 100 cases without a death. He wrote a number of articles on this subject, and his work was widely appreciated, especially by those in the hides and tannery industries. Dr. Hodgson was a vice-president of the Liverpool Medical Institution and was also lecturer on infectious diseases in Liverpool University. He

retired in August, 1946. Hodgson was of a gentle and affectionate disposition and was universally popular with patients and their relatives, with the hospital staff, and with the profession. One sister survives him.

Dr. WILLIAM JOHN LEACH, of Beaulieu, Inverness-shire, died suddenly on Jan. 9 at the early age of 48. After graduating M.B., Ch.B. at the University of Aberdeen in 1924, and holding an appointment as house-surgeon in the Sick Children's Hospital there, he returned home to take over the practice of his father, Dr. John Leach, in Beaulieu. The "young doctor" soon endeared himself to the patients in his practice, which covered an extensive country area and included a large proportion of work under the Highlands and Islands Medical Service. His visits necessitated many arduous journeys to the hills and glens, and required no little physical endurance as well as skill and ingenuity in the home management of isolated cases. In the busy life of a country doctor he found time to keep up to date with medical literature, and was an enthusiastic attendant at clinical meetings. A keen member of the British Medical Association since 1928, Dr. Leach was president of the Northern Counties of Scotland Branch from 1939 to 1946; he represented the Inverness Division at annual representative meetings in 1938 and 1943, and was a member of the Insurance Acts Committee and of the Scottish Subcommittee of the Insurance Acts Committee for several years. Dr. Leach, who was greatly interested in many forms of sport, was a good horseman and was also commodore of the Beaulieu Firth Yacht Club. A genial companion, a man of generous impulse and ever anxious to help in the furtherance of any good object in his community, Dr. Leach was held in high esteem by a wide circle of friends in the Beaulieu district, and his death will be felt as a deep loss by them. He is survived by his widow and daughter, to whom the sympathy of his colleagues will be extended.

Dr. VALENTINE HENRY BLAKE died suddenly on Jan. 10, at the age of 67, at his home in Great Yarmouth. He was the elder of the two sons of the late Dr. Henry Blake of that town; the younger brother is Major-General H. H. Blake, late A.M.S. Valentine Blake was educated at Yarmouth and at Bedford. He gained an entrance scholarship at St. George's Hospital, London, and graduated as M.B., B.S. in 1905. He was house-surgeon at St. George's, and afterwards at the Cancer Hospital, Fulham Road. He then joined his father in practice in their home town. He was honorary surgeon to the Great Yarmouth Hospital from 1909 to 1946, and all his work was characterized by single-minded devotion to his duty and his patients. On retiring, he was appointed honorary consulting surgeon. In 1947 Dr. Blake had to retire completely from practice because of a dissecting aneurysm and, coronary thrombosis which together caused his untimely death. During the first world war he served in the R.A.M.C. in Egypt and in France, and was mentioned in despatches. He had been a certifying surgeon under the Factories Acts and Trinity House medical officer for the Yarmouth district. In 1933-4 he was president of the Norwich Medico-Chirurgical Society and in 1942-4 of the Norfolk Branch of the B.M.A. In all these varied activities Blake displayed the qualities of earnestness, keenness, and intelligence which he had shown in his student career. Nothing was too much trouble for him, particularly during the grim days of air raids. In earlier days he was prominent as a swimmer and a motor-cyclist, at both of which sports he won trophies. In later years he was a proficient shot and fisherman. Dr. Blake married, in 1926, Enid, daughter of Dr. Hedley Bartlett, of Saffron Walden, who survives him with their two sons and one daughter; the elder son proposes to enter his father's profession.

Dr. EDWIN LEONARD LEES, of Clifton, Bristol, died on Jan. 10 at the age of 85. He was born at St. Andrews, and his father was a surgeon in the I.M.S. who died of typhoid fever at the early age of 36. His medical education was at Edinburgh and Bristol. He graduated M.B., C.M. at Edinburgh in 1885, and proceeded M.D. in 1890. He came south to Bristol in 1884, and on qualifying went into general practice as an assistant to Dr. Coleman. For sixty-one years, until his retirement in 1945, he was in charge of a large general practice, the arduous duties of which he carried out with entire unselfishness and devotion. Dr. Lees was a man of strong personality who took the greatest interest in his patients, to whom he was not only a doctor but a guide and friend. In addition to his general practice he had a particular interest in the diseases of children. He held in succession the appointments of house-surgeon, registrar, and physician on the staff of the Royal Hospital for Sick Children and Women in Bristol, being appointed consultant physician on his retirement. There are many who will regret the loss of

a friend and counsellor and who will deeply sympathize with his widow and the six children who survive him.

Dr. HUGH HOWIE BORLAND, who was 91, died on Jan. 12 after a long illness. He graduated M.B., C.M. at Glasgow in 1896, and took the Cambridge D.P.H. in 1899. After holding resident appointments at the Western Infirmary, Glasgow, and at the Maternity Hospital, he went into general practice in the Dennistoun district of Glasgow, and became one of the clinical tutors at the Royal Infirmary. In the first world war he acted as medical officer at Duke Street prison. The fact that Dr. Borland was elected Deacon of the Incorporation of Barbers testifies to the respect in which he was held by his fellow citizens. He was an elder of St. John's Church, Renfield, and in other ways showed his interest in religious work. He was a man of high personal character, a kind friend, and a loyal colleague.—T. K. M.

Dr. PERCY ARTHUR STOREY died at his home in London on Jan. 16 at the age of 79. Dr. Storey was educated at Brighton College and University College, London, and qualified M.R.C.S., L.R.C.P. in 1894. In 1918 he graduated M.D. of the University of Durham. Always a general practitioner, he practised in St. Marylebone for fifty-four years until his retirement about two years ago. His work there was interrupted only when he served in the R.A.M.C. in the 1914-18 war. During the recent war he worked with the Marylebone A.R.P. services. He was a member of the Harveian Society of London and of the Chelsea Clinical Society. A Fellow of the Zoological Society of London, he took a great interest in animals, and he had a particularly fine collection of butterflies.

Dr. LOUISE WHITMAN FARNAM WILSON died at Hove on Jan. 21. She received her medical education and graduated M.D. at the University of Yale in 1920. She then started work in the mission field in China at the Hunnan-Yale Medical College. She got great satisfaction from that work, and in the course of it met her English husband. Returning with him to this country she spent the next two years studying for the L.R.C.P. and M.R.C.S., which she took in 1936. Dr. Wilson then undertook temporary work in general practice in London. Shortly afterwards she helped in some research work with Dr. Leonard Colebrook. At the outbreak of war she settled down in rural general practice in Sussex. In recent years she bore with great patience and fortitude a long and trying illness. Louise Wilson had the freshness of outlook of the American combined with a determined desire to get to the bottom of any subject which interested her. In the most gentle manner she would enunciate the boldest ideas, but she was tolerant of criticism and in fact eager for it. The crowded congregation at the memorial service at Keymer Church on Jan. 29 showed well the devotion of her old patients, many of whom had come long distances in order to be present.

Professor R. J. Willan writes: The sudden death of Mr. Stanley Raw (*Journal*, Jan. 22, p. 158) caused widespread regret in Sunderland and in the North of England, where he had an extensive and successful surgical practice. Until recently Mr. Raw was senior surgeon to the Royal Infirmary, Sunderland, and to the Sunderland Municipal Hospital. To both hospitals he rendered yeoman service, both clinically and administratively. A man of sound clinical judgment, an operator of outstanding merit, he was also an acceptable lecturer and teacher. He was an ideal chief of a clinic, for he took a great personal interest in his juniors, whom he so ably guided and encouraged in their work. He had a large practice associated with the Workmen's Compensation Act, particularly among the Durham coal-miners. There was a remarkable mutual understanding and respect between him and his collier patients, and Raw's opinion was seldom challenged, and if challenged was seldom held to be in the wrong. He was a fellow of the Association of Surgeons of Great Britain and Ireland. He took a prominent part in the amalgamation of the Northumberland and Durham Medical Society with the Newcastle Clinical Society, which then became the present Newcastle-upon-Tyne and Northern Counties Medical Society. In due course he became president of the new society, and his scholarly presidential address, "Handing on the Torch," is still remembered with pleasure. Apart from his professional eminence, his life included many interests. He loved climbing, travelling the oceans, sailing small boats, and was a golfer with a low handicap. He was very happily married, and his wife shared his many interests. A man of commanding stature and great physical strength, he had climbed the mountains of many

countries. Recently, during a South Atlantic pleasure cruise, he visited the island of Tristan da Cunha, where he had the unusual experience of climbing the 7,640-ft. mountain of the island, a feat that, through lack of opportunity and lack of dependable weather conditions, cannot often have been performed by a visitor. His generosity was proverbial among his friends, and probably no one in need ever asked his help in vain. He had a keen sense of humour, was exceptionally well read, had a fund of good stories, and could be relied upon as a witty after-dinner speaker. So there has passed a man of outstanding character, a man full of humanity, and a great gentleman whom it was an honour to have known. Mrs. Raw can be assured of the sincere sympathy of his many friends in her irreparable loss.

Dr. R. W. Lee writes: I was grieved beyond measure to read of the death of Dr. William Susman (*Journal*, Jan. 8, p. 76), and should like to pay tribute to him as I knew him many years ago. We served together in the same infantry company in France in 1917 and 1918 as very junior officers. Inevitably he was known as "Susie," and it was always a treat to hear his platoon singing a popular song relating to a certain "Sister Susie" as they followed him on a march. With his rich Canadian slang, no doubt toned down in later years, a gaiety that persisted at all times, and courage of a high order, he was a much-loved figure. A handy man with his favourite weapon, the Lewis gun, he achieved fame as a gunman, Wild West type, by a fluke in which he smashed the company commander's walking-stick with a revolver at twenty paces. The owner's wrath and the marksman's joy were roughly equal. In one typical exploit he disobeyed strict orders when, alone and unarmed, he explored an unhealthy no-man's-land on a dark, wet night in search of a reconnaissance patrol that had been given up as lost. By another fluke contact was made, and he led them home rejoicing on a route laid down by a ball of string. It is in particular gratitude for that action, involving very great risk, that I wish to record some appreciation of Susman as a very gallant officer.

Medico-Legal

PENSION AFTER HUSBAND'S SUICIDE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

he law concerning war pensions establishes a strong presumption in favour of the applicant that the condition of disability (or death) is the result of service. In a disputed case the Minister of Pensions has to prove the negative, often a very difficult task.

In *Duff v. Minister of Pensions*, a recent Scottish case,¹ a Glasgow tram driver who had been concerned in a fatal accident had a nervous disturbance and gave up his job. Next month he was called up for military service but deferred for six months. When this period had elapsed he was drafted into the infantry, and two weeks later his body was found in the sea. There was no doubt that he had committed suicide. His widow claimed a pension, but her application was refused and her appeal to the tribunal rejected. She then appealed to the Court of Session, and won.

Lord Thomson, the Lord Justice Clerk, observed that the pensions tribunal had held it proved that the deceased had committed suicide because he was depressed when he enlisted, that the depression was a continuation of a pre-Service psychotic illness from which he had never recovered. The tribunal had also held that his very brief Army life had been happy. His Lordship's brother judges and he could not help feeling that there was involved in that cryptic finding the idea that there was need only to establish that the deceased's Army life had been such as would not upset a normal man. The court did not think that this was the proper test. The test must be an individual test, and the tribunal must ask itself what was the effect of Service conditions on this particular man. There was no evidence to enable the court to affirm that Service conditions had not played a part in aggravating the man's depression and so precipitating the tragedy. The court therefore allowed the appeal and the widow gained her pension.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on Dec. 16, 1948, the following degrees were conferred:

D.M.—A. E. Mourant.
B.M.—H. E. Reiss, D. F. Mullins, M. H. Hall, *Mrs. Joan W. Kipling, *Janet E. McKinstry.

* In absentia.

UNIVERSITY OF CAMBRIDGE

The medical committee of the Board of Governors of the United Cambridge Hospitals has elected Claude Howard Whittle, M.D., F.R.C.P., a member of the Faculty Board of Medicine for the two years ending Dec. 31, 1950.

The following degrees were conferred in Congregation on Jan. 21:

M.A.—Joan Mary Boissard, M.R.C.S., L.R.C.P., University Assistant Director of the Public Health Laboratory, and James Wilson Millen, M.D., University Lecturer in Anatomy.

M.B., B.Ch.—*G. C. Myddelton, G. R. Hervey, *R. D. Affen, *C. B. McKerrrow, *J. G. O. W. Yerburch, *G. P. Blanchard, *Alexis Brook, *D. R. Harrocks, *A. R. H. Hicks, *P. H. Lord, *F. R. Ryle, *K. H. L. Scougall, *J. B. Howells, *J. C. Wardill, *J. L. Millard, *R. A. Rowan, E. W. Heining, *J. A. Balint, *T. M. Robinson, *C. D. Thompson, *N. P. L. Wildy, *A. L. Wells, *Wright, L. Linder, *H. E. Flint, *R. S. Smith, *T. J. D. Walker, *A. L. Wells, *K. W. Leech, *J. V. Earle, *J. D. Llywelyn-Jones, *T. B. Boulton, *R. D. Cundall, *P. G. R. Dench, *G. A. D. Lavy, *G. M. Jones, T. H. H. Wade, *J. R. Edsall, *June Bean, *Daphne E. Lewin.

* By proxy.

UNIVERSITY OF GLASGOW

At a Graduation Ceremony held on Jan. 15, the following medical degrees were conferred:

M.D.—G. C. Arneil, K. C. Hutchin, A. W. Lees, G. Leslie, J. S. Stevenson.

M.B., Ch.B.—A. H. Alexander, C. I. S. Bartlett, Mary P. S. Borland, Lucy McL. C. Boyd, Mary B. S. Calder, A. Carnochan, Mary E. Catto, Agnes A. Coughtrie, R. McL. Douglas, W. I. L. Fraser, G. L. Gibson, D. A. Haldane, Mary M. Hamilton, A. C. Howie, A. N. Hunter, B. Joels, *Elizabeth M. S. Kilpatrick (Mrs. Wotherspoon), Anne K. Kirkland, D. A. Knox, R. R. Lang, D. McC. Macgregor, J. MacKay, A. M. Mechie, A. P. Miller, A. R. Morrison, J. Morton, J. J. Mullen, P. R. Probert, J. D. Read, H. A. Roemmele, L. Rose, Christina C. Stevenson, I. O. Stewart, J. Stewart, J. A. M. Stewart, R. E. Stewart, W. S. Stoddart, P. Stuart, H. W. Thomas, D. B. Turnbull, J. M. Uku, J. Wright.

* In absentia.

UNIVERSITY OF MANCHESTER

William Ian Clinch Morris, M.B., Ch.B., F.R.C.S.Ed., M.R.C.O.G., has been appointed whole-time Professor of Obstetrics and Gynaecology and Director of the Department, in succession to the late Professor Daniel Dougal.

UNIVERSITY OF WALES

The following candidates for the degrees of M.B., B.Ch. at the Welsh National School of Medicine have satisfied the examiners at the examinations indicated.

HYGIENE.—Lilian J. Cunningham, H. B. Jenkins, Nano J. Morgan, D. St. J. D. Rees.

OBSTETRICS AND GYNAECOLOGY.—Marjorie J. Adams, Mary P. E. Alban, F. W. Beswick, M. L. Cattell, R. B. Davies, Elizabeth B. Dew, D. C. Dymond, L. Elton, A. R. Evans, K. Gammon, P. H. Griffiths, E. I. Gwynne, G. E. Heard, J. I. Hopkins, June D. James, H. B. Jenkins, Ruth E. Lewis, M. G. Lloyd, Nano J. Morgan, Rhona E. Morgan, B. Phillips, H. M. N. Rees, J. A. E. Richards, R. M. Richards, *D. C. Saunders, J. A. Stanton, D. G. H. Thomas, E. Thomas, J. D. Thomas, J. G. H. Thomas, S. Thomas.

SURGERY.—Mary P. E. Alban, *F. W. Beswick, M. L. Cattell, Elizabeth B. Dew, L. Elton, E. H. Evans, K. Gammon, P. H. Griffiths, G. E. Heard, June D. James, T. D. Jones, Ruth E. Lewis, M. G. Lloyd, Rhona E. Morgan, B. Phillips, J. A. E. Richards, R. M. Richards, *D. C. Saunders, C. P. Seager, J. A. Stanton, Brenda M. Thomas, E. Thomas, J. G. H. Thomas.

* With distinction.

The following candidates at the Welsh National School of Medicine have satisfied the examiners at the examination indicated:

DIPLOMA IN PUBLIC HEALTH.—I. A. Bolz, J. W. Bowen, R. Glenn, F. J. Hallinan, F. C. R. Harvey, *R. A. N. Hitchens, Amelia Rowles, G. F. J. Thomas.

* With distinction.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a meeting of the College held on Jan. 27, with the president, Lord Moran, in the chair, Sir W. Dalrymple-Champneys was elected to represent the College at the Health Congress of the Royal Sanitary Institute, to be held at Brighton from May 23 to 27, and Professor A. A. Moncrieff was re-elected representative on the Colonial Medical Advisory Committee.

Membership

The following candidates, having satisfied the Censors' Board, were elected Members:

D. M. Abelson, M.B., L. E. Arundell, M.B., J. Badenoch, B.M., R. G. Benians, M.B., E. R. Bickerstaff, M.D., J. D. Blainey, M.B., J. P. P. Bradshaw, M.B., B. C. Brown, M.D., P. E. Brown, M.B., Flight Lieutenant, R.A.F.M.S. Alice M. Bush, M.B., R. J. Calvert, M.B., K. M. Chalmers, M.B., J. B. Cochran, M.B., J. S. Crowther, M.B., D. Davies, M.B., J. F. Delafresnaye, M.D., E. M. C.

Dunlop, M.D., T. B. Dunn, M.B., G. F. Edwards, M.B.E., M.B., Major, R.A.M.C., H. L. English, M.B., O. D. Fisher, M.B., R. M. Forrester, M.B., J. M. Garvie, B.M., P. B. Gatenby, M.B., H. J. Goldsmith, M.B., A. Grant, M.D., A. P. Grant, M.D., L. J. Grant, M.B., I. Grayce, M.B., C. W. E. B. Greaves, L.R.C.P., D. McK. Hanna, M.B., T. D. B. Hanratty, M.D., P. L. de V. Hart, M.B., F. G. J. Hayhoe, M.B., B. C. Henderson, M.B., A. C. S. Hobson, M.C., L.R.C.P., Major, R.A.M.C., G. K. M. Hodgkin, B.M., K. S. Holt, M.B., J. N. Horne, M.D., W. M. Irwin, M.B., E. W. Jackson, M.D., D. V. M. Jones, L.R.C.P., N. B. Jones, M.B., P. G. Jones, M.B., E. W. Jackson, M.D., D. V. M. Jones, L.R.C.P., Khan, M.B., L. G. Kiloh, M.B., R. I. Meanock, M.B., R. I. Meanock, M.D., A. P. Meiklejohn, M.D., C. Merskey, M.D., M. J. Meynell, M.D., E. F. D. Montuschi, M.D., D. Morris, L.R.C.P., B. K. Naik, M.B., L. D. Osler, M.B., R. T. Parkin, M.B., J. Pepys, M.B., G. W. Poole, M.B., S. R. Reader, M.B., E. A. Ritchie, M.B., A. J. Robertson, M.B., L. J. Rowley, M.B., E. Sanders, M.D., L. G. Scott, M.B., K. R. Shroff, M.B., J. A. Simpson, M.B., S. Smith, M.D., A. E. Thomas, M.B., A. D. Thomson, M.B., D. O. Trounce, M.B., J. S. Watson, M.B., R. W. E. Watts, M.B., Captain, R.A.M.C., I. G. Wickes, M.B., J. R. Wilson, M.B., R. A. Womersley, M.B.

Licences

Licences to practise were conferred upon the following 134 candidates (including 27 women) who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and who have complied with the necessary laws:

L. A. Adams, Mari Ainsleigh-Jones, R. D. Allen, A. Allibone, D. W. Aniss, Mary P. Armstrong, Patricia Arnold, H. W. Bain, J. A. Balint, A. A. Bartholomew, D. A. A. Beardmore, T. Bell, L. C. Bellsham-Revell, J. F. Bennett, C. A. Biscoe, I. F. Bishop, J. B. F. Boyle, Maria E. B. Brennan, Sylvia M. Brown, T. W. Brown, T. V. Campkin, J. Cantor, J. W. Cieszyński, K. M. Citron, W. E. Clifford, O. F. Conran, G. A. Coombs, F. H. Corbitt, E. H. J. Cotter, Patricia O. Currie, T. A. Daff, Shirin Dastur, G. L. Davies, Joyce M. Daws, J. M. Dodd, G. H. Dunkerley, Audrey M. Emmerson, J. B. C. Eveleigh, J. G. Fairer, O. Fleischer, H. E. Flint, Margaret Ford, A. T. T. Forrester, P. G. Fox, Elizabeth M. France, Jean M. Gibson, J. G. Gill, U. S. Gill, R. G. Godfrey, M. M. Gollow, A. J. Graham, J. C. Graham-Stewart, M. Grant, Margaret I. Green, D. G. G. Greenaway, Wendy E. Greengross, D. H. Griffiths, A. K. Hancock, D. T. C. Harris, Kathleen J. Harrison, Gladys F. Horton, E. T. Hughes, T. J. M. Hughes, D. S. Hurwood, J. M. E. Hyde, B. Jacobs, A. V. Jenkins, D. G. Jenkins, I. M. Jones, G. Keen, P. W. L. Kelly, M. Lauchlan, Joan E. Lewis, T. McKendrick, D. J. Mantle, Ida Mather, A. H. Mendoza, G. G. Meynell, J. L. Millard, R. Mitchell, G. W. Moore, J. H. S. Morgan, D. Morris, B. C. Morson, G. V. Mulholland, J. G. B. Myles, C. Nagrath, E. J. Newton, J. G. Noble, K. Orr-Hughes, O. N. H. Owen, N. C. S. Owen, Joyce M. Parker, J. E. Phillips, S. Plimpton, B. Pollak, K. G. Prior, D. S. R. Charlson, I. H. Richardson, R. E. Richardson, Kathleen M. Roby, P. Ronchetti, P. T. C. Rowan, J. E. Russell, G. W. Scott, B. M. Sellars, F. M. M. Shattuck, Muriel E. Sidaway, A. Southwell, H. W. Stanley, Ursula Stanley, A. E. Steel, R. R. Stenham, Sara I. Stinson, Elizabeth J. Sutton, Brenda A. Taylor, C. W. Taylor, G. B. Taylor, Mavis B. Taylor, J. N. R. Toke, D. O. Topp, G. J. Van Klaveren, I. S. Waller, R. D. Walsh, A. J. Walters, Monica Watson, P. S. Watson, J. D. Wheatcroft, I. C. L. White, D. A. G. Williams, J. D. Williams, T. E. Williams, G. T. Woods.

Diplomas

Diplomas in Anaesthetics, in Psychological Medicine, in Tropical Medicine and Hygiene, in Laryngology and Otology, in Medical Radio-Diagnosis, in Public Health, in Industrial Health, and in Medical Radiotherapy were granted jointly with the Royal College of Surgeons of England to the following successful candidates:

DIPLOMA IN ANAESTHETICS.—D. Davies, G. Kerr, and R. Sturton, and to the 34 successful candidates whose names are printed in the report of the meeting of the Royal College of Surgeons of England in the issue of Jan. 1 (p. 38).

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—B. W. Richards and to the 24 successful candidates whose names are printed below in the report of the meeting of the Royal College of Surgeons of England.

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—To the 3 successful candidates whose names are printed in the report of the meeting of the Royal College of Surgeons of England in the issue of Jan. 1 (p. 38).

DIPLOMA IN LARYNGOLOGY AND OTOTOLOGY.—H. J. Doran, R. M. Harvey, D. J. Heffernan, A. R. Rowe, J. L. Wakelin, T. C. Fort, J. B. O'Mahony, and R. C. J. Rustomjee, and to the 21 successful candidates whose names are printed below in the report of the meeting of the Royal College of Surgeons of England.

DIPLOMA IN MEDICAL RADIO-DIAGNOSIS.—D. M. R. Barry and J. W. Pierce and to the 21 successful candidates whose names are printed in the report of the meeting of the Royal College of Surgeons of England in the issue of Nov. 27, 1948 (p. 964).

DIPLOMA IN PUBLIC HEALTH.—R. Alexander, H. J. Anderson, R. L. Chopra, D. Coughlan, C. D. Edwards, B. M. George, D. E. Jeremiah, B. G. Johnson, A. P. Kalra, A. P. R. Lewis, D. K. L. Lindsay, W. D. H. McFarland, C. W. Maisey, Dorothy K. Paterson, F. O. Potter, Annie F. G. Rowlands, Joan N. Ruben, Victoria W. D. N. Shaw, Margaret S. Stevenson, R. N. E. Watt, P. West, J. L. M. Whitbread.

DIPLOMA IN INDUSTRIAL HEALTH.—J. W. Webb and to the 16 successful candidates whose names are printed below in the report of the meeting of the Royal College of Surgeons of England.

DIPLOMA IN MEDICAL RADIO-THERAPY.—P. B. Woodyatt and to the 15 successful candidates whose names are printed in the report of the meeting of the Royal College of Surgeons of England in the issue of Nov. 27, 1948 (p. 964).

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on Jan. 13, 1949, with Lord Webb-Johnson, President, in the chair, Professor J. R. Learmonth was admitted to the Honorary Fellowship.

Mr. J. E. Piercy (London), Professor V. F. Lambert (Manchester), Mr. Norman Hodgson (Newcastle-upon-Tyne), and Mr. G. H. Buckley (Blackpool), being Fellows of the Royal College of Surgeons of Edinburgh, were elected *ad eundem* to the Fellowship.

Drs. George Feneley, A. Parry Brown, H. Grant-Whyte, and Geoffrey Kaye were elected Fellows of the Faculty of Anaesthetists.

A Diploma of Membership was granted to D. N. H. Owen and I. S. Waller.

A Diploma of Fellowship was granted to A. G. Jessiman. Diplomas were granted jointly with the Royal College of Physicians of London as follows:

MEDICAL RADIO-DIAGNOSIS.—D. M. R. Barry.

ANAESTHETICS.—R. V. Sturton.

INDUSTRIAL HEALTH.—W. Blood, L. B. Bourne, J. A. Harrington, A. K. Hill, W. T. W. Lawson, R. F. L. Logan, A. C. Mackay, G. Milne, J. G. Mon, H. Mukhopadhyay, A. J. Patterson, J. R. Sen Gupta, G. Taylor, Margaret E. Thwaites, T. E. M. Wardill, N. Williams.

LARYNGOLOGY AND OTOTOLOGY.—G. G. Allan, M. D. Grenin, K. H. Dalrymple, P. G. Jay, P. K. Khasnobis, R. M. Lang, H. A. J. Lister, I. Lopez, W. P. McKechnie, V. St. J. de C. Magian, W. H. Mirkin, Constance B. S. Napier, M. M. Nath, S. S. Ovanessoff, W. M. Owen, R. E. Peasegood, A. Schiller, C. T. Tang, R. H. Welch, T. J. Wilmot, I. S. Young.

PSYCHOLOGICAL MEDICINE.—J. C. Baillie, R. F. B. Bennett, F. H. Bodman, E. A. Burkitt, F. R. M. Calder, S. Catterall, G. I. Davies, R. H. Geman, J. K. Hewat, R. M. Jones, F. J. Kelleher, H. Lantin, I. Levison, A. Limerani, S. C. MacMillan, J. W. Macpherson, D. H. D. Paine, R. A. Sandison, R. B. Taylor, W. N. Taylor, D. C. Watt, A. Wood, C. M. Xavier, F. L. D. Young.

Arrangements are being made for a combined course of lectures and clinical conferences, in relation to the surgery of childhood, to be held in London from July 4 to 8. Clinical conferences will be held each morning at selected children's hospitals followed in the afternoons by lectures at the College. The fee for the course will be £12 12s. or £10 10s. for Fellows and Members of the College and full-time students of the Institute. Further details will be announced in due course. Meanwhile applications, accompanied by a remittance, may be sent to the secretary, Postgraduate Education Committee, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2, or to the secretary, Institute of Child Health, the Hospital for Sick Children, Great Ormond Street, London, W.C.1.

The Services

The President of the U.S.A. has conferred the following decorations in recognition of distinguished services in the cause of the Allies:

Officer of Merit, Degree of Officer.—Colonel L. C. Montgomery, O.B.E., M.C., R.C.A.M.C.

Legion of Merit, Degree of Legionnaire. Bronze Star Medal.—Captain C. T. Robertson, M.B.E., R.C.A.M.C.

NORTH PERSIAN FORCES MEMORIAL

The North Persian Forces Memorial silver medal for 1947 has been awarded to J. N. P. Davies, M.B., Ch.B., for his paper entitled "The Pathology of Central African Natives," published in the *East African Medical Journal*. The medal is awarded every year for the best paper on tropical medicine or tropical hygiene in any journal during the twelve months ending Dec. 31 by any medical officer of under twelve years' service in the R.N., the R.A.M.C., the R.A.F., or the Colonial Medical Service. The memorial was founded by officers of the R.A.M.C. and other Service medical officers who served with the North Persian Forces in the first World War.

DEATHS IN THE SERVICES

Lieutenant-Colonel JOHN WEMYSS GRANT died on Jan. 11 at the age of 79. After thirty years in the Indian Medical Service he retired to Broadstairs in 1931. He graduated from Aberdeen University in 1892 and on arrival in India was posted to the Royal Indian Marine survey ship *Investigator* as zoologist and medical officer. After a voyage in the *Investigator* Grant became medical officer to the 15th Sikhs and went through the Chitral expedition with them. He was later transferred to the political department. At different times he was residency surgeon to the Kingdom of Nepal, Muscat in the Persian Gulf, Bhopal in Central India, and Jodhpur in Rajputana. Most of his service was spent in the last-named State, which covers an area the size of Ireland. On completing his service he had the unusual honour of being presented with an illuminated address in an ivory casket. The ceremony took place in the centre of Jodhpur city in order to give everyone, from the highest to the poorest, the opportunity to bid farewell to their much-loved and respected friend. Colonel Grant's name appeared in the first list of recipients for the newly created Kaiser-i-Hind medal for distinguished public service in India. He earned the award during the great famine. The Maharajah of Nepal also bestowed on him the Order of the Star of Nepal, a distinction rarely given to foreigners. In the first world war Colonel Grant commanded an Indian General Hospital, first in Brighton and then in Mesopotamia. On the outbreak of hostilities in 1939 he was already serving on a medical board in Canterbury and later was given the task of organizing the medical arrangements for the Home Guard in the Thanet area. After undergoing a severe operation in 1943 his professional activities ceased. He leaves a widow, Mrs. Lilian Grant, who is a doctor.

Medical Notes in Parliament

Last N.H.I. Payment

On Jan. 27 Mr. BESWICK asked the Minister of Health when he expected to make a final payment under the former National Insurance Scheme to medical practitioners in Middlesex.

Mr. BEVAN answered that executive councils had been notified of the amounts available for the final payments to doctors in respect of medical benefit under the National Health Insurance Acts and had been asked to make the necessary payments to doctors as soon as possible.

Cost of N.H.S.

Sir THOMAS MOORE asked on Jan. 27 for the latest estimate for the current annual cost of the National Health Service, as divided amongst the main branches, together with the administration costs; and also for figures indicating the estimated income from contributors.

Mr. BEVAN replied that a supplementary estimate of the cost of the National Health Service for the period July 5, 1948, to March 31, 1949, divided among the main branches would shortly be laid before the House. The amount available from National Insurance contributions towards the cost of this Service was estimated to be £24,000,000 for the same period.

Teaching Hospitals in Scotland

Miss HERBISON asked on Jan. 25 which hospitals had been added to the list of teaching hospitals in Scotland since June, 1946.

Mr. WOODBURN replied that the bulk of medical teaching in Scotland was carried on in a few large general hospitals in the four centres Aberdeen, Dundee, Edinburgh, and Glasgow. The main teaching hospitals remained as in June, 1946. There was, however, an increasing use of other hospitals for teaching purposes both in the four centres and outside. In the interests of the hospital service as well as teaching, he was anxious to encourage this extension. Medical education committees to advise the regional hospital boards on this and other aspects of the provision of facilities for clinical teaching were about to begin work in each region.

Salaries of Medical Officers of Health

Mr. KEENAN on Jan. 27 asked Mr. Bevan what steps he proposed to take to help or assist local authorities to secure and retain the services of medical officers now that the salaries paid and offered were considered insufficient since the operation of the Health Service Act of July last.

Mr. BEVAN declared that, while expressing no view on the adequacy of these salaries, he was ready to join with the local authorities in establishing a Medical Whitley Council on which they could be discussed.

Antrycide

Mr. HALE asked on Jan. 26 for a statement on the use of "antrycide" in Africa.

Mr. CREECH JONES answered that field trials conducted throughout 1948 in Kenya, Uganda, and the Sudan showed that a single treatment with the new drug cured the two most important trypanosome diseases in cattle, *T. congolense* and *T. vivax*. It had also proved effective against trypanosome diseases which affected camels, horses, dogs, and pigs. In addition to its curative properties, antrycide afforded protection against trypanosome diseases. Trials were continuing to establish the duration of the period of protection. Limited supplies of the drug had been made available to Government veterinary departments in Africa. It was in use in Kenya, Uganda, and Nigeria (as well as in the Sudan). The effectiveness of the drug, particularly its prophylactic properties, would, it was hoped, improve the prospect of increased meat production in areas of Africa hitherto closed to domestic animals or precarious for them. He was examining the veterinary, agricultural, administrative, and other aspects of the development of animal husbandry in Africa made possible by the discovery of the drug. Initially it would be used to afford protection on stock routes and during seasonal migrations, but as supplies became more plentiful it was proposed to use it in combination with other methods of control to expand the present cattle-rearing areas. He was not in a position at this stage to estimate its ultimate effect on meat production in Africa.

Female Circumcision

Mr. HECTOR McNEIL said on Jan. 26 that he had no precise information about the prevalence of female circumcision in the Sudan. He was assured that legislation passed in 1926 and the subsequent propaganda had checked this repulsive and harmful practice. Progress, however, in the face of such a long-established tradition was regrettably, if necessarily, slow.

INFECTIOUS DISEASES AND VITAL STATISTICS

No. 2

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Jan. 15.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Influenza

There has been no important epidemiological change since week. Deaths from influenza in the great towns in the ended Jan. 22 numbered 45, as against 40 in the previous . These are very low figures for this time of year. There been a few more reports of small outbreaks of a disease appears on clinical grounds to be true epidemic influenza mild type. At least one of these could be directly associated with an importation from the Continent. No large outbreaks have been reported.

A large number of specimens of virus obtained from abroad and cases in this country is proceeding, but final results are not available. From preliminary tests, however, it appears the virus responsible may be the variant of virus A which appeared in this country at the beginning of 1947. If this is here may be good reason to hope that some measure of unity still lingers in the population of England and Wales that a serious epidemic is unlikely.

read in Europe.—According to reports reaching the World Health Organization up to Jan. 18, Albania, Ireland, and Portugal have had only a few mild cases. Cases of influenza noted in mid-December in Bulgaria have been characterized by their remarkably mild but prolonged character and mainly affected very young children and the aged.

Jan. 14 almost the whole territory of France had been involved in an epidemic which affected about 20% of the population. Although generally of a mild type, the disease has caused a certain number of serious, and even fatal, cases, particularly among very young children and old people.

Cases have been sporadic and of a mild character in Greece and Poland. In Switzerland thirteen cantons have been affected, particularly Tessin, Geneva, Schaffhouse, and Basle city.

Identification of Viruses.—Virus A was identified in 50% of specimens taken from patients in the Lyons region. A virus also isolated which does not appear to belong to either A or type B, and work on the identification of this virus is proceeding at the Pasteur Institute in Paris. More recent information suggests that the prevalent French strain corresponds with the virus isolated in Holland, and this is probably identical with the Italian strain.

Influenza virus A has been identified in the southern part of land by Professor J. Mulder, of the University of Leiden. The subtype is not clear, and is probably not PR8, but seems likely to be closely related to the 1947 A strains which caused large epidemics in Sweden and small epidemics in land, England, and America.

Discussion of Table

In England and Wales there were decreases in the notifications of measles 2,263, diphtheria 34, and scarlet fever 33, with increase in the notifications of whooping-cough 519.

The largest declines in the notifications of measles were in Lancashire 681, Yorkshire West Riding 668, Nottinghamshire 1, and Essex 94; in contrast to this general decline, increases were recorded in Staffordshire 73 and Yorkshire East Riding 68. Notifications of diphtheria gave the lowest weekly total ever recorded and were 8 below the previous record low level. The centres of diphtheria during the week were Lancashire 20, Thames 13, London 11, Warwickshire 9, and Cheshire 8; the remaining 31 notifications were distributed over sixteen counties. Increases in the incidence of whooping-cough were recorded in Lancashire 121, Staffordshire 64, Warwickshire 55, Leicestershire 46, and Middlesex 40.

The largest returns for dysentery were London 27 (St. Pancras and Lancashire 17 (Liverpool C.B. 6 and Oldham C.B. 5). Notifications of acute poliomyelitis increased by 15, and multiple cases were recorded in Kent 5; Middlesex 5 (Harrow D. 2); London 4 (Southwark 2); Lincolnshire 3; Wiltshire 2; Buckinghamshire 2; Essex 2; and Lancashire 2 (Manchester 3, 2).

In Scotland there was an increase in the notifications of whooping-cough 163, measles 47, scarlet fever 43, acute primary pneumonia 41, and dysentery 11.

In Eire there was a decrease of 13 in the notifications of diphtheria.

In Northern Ireland the chief feature of the returns was an increase of 22 in the notifications of whooping-cough. Notifications of measles increased by 32 in Tyrone county, while in the remainder of the country a decrease of 24 was reported.

Week Ending January 22

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,311, whooping-cough 42, diphtheria 131, measles 10,254, acute pneumonia 1,050, rebrsopinal fever 24, acute poliomyelitis 26, dysentery 104, ratyphoid 1, and typhoid 3.

Medical News

A 110th Anniversary

A dinner to celebrate the 110th anniversary of the *Medical Press* was held in London on Jan. 26. It was presided over by Sir Cecil Wakeley, the present editor, and was attended by about 60 guests, including Lord Moran, Lord Horder, Sir Edward Mellanby, Sir Wilson Jameson, and the editors of the *British Medical Journal* and the *Lancet*, and many others identified to a greater or less degree with medical journalism. A portrait dated about 1819 of Arthur Jacob, the founder and first editor of the *Dublin Medical Press*—the original title—and a number of personal relics relating to him and to the second editor, his son, Archibald Jacob, were exhibited. Lord Moran, in proposing the health of the journal, said that one of the remarkable features of the early issues of the *Medical Press* was its insistence upon freedom. Sir Cecil Wakeley, in reply, said the *Medical Press* differed from many other medical journals in various respects—for one thing, its editors had always been men in clinical practice—but like its contemporaries it had stood throughout its history for freedom of expression of opinion.

Dr. H. Guy Dain, proposing the toast of "Medical Journalism," said that one of the things of which the medical profession could be most proud was that it did not seek any "closed shop" for its information. Any new development or discovery was immediately published to the whole world, and nobody attempted to make any profit out of it for himself. The medical journals of Great Britain stood comparison with those of any other country. If they were, on the whole, cautious and conservative, that was a fault on the right side. Sir Heneage Ogilvie, editor of the *Practitioner*, responding, observed that the medical journals, serving the most highly educated, critical, and diverse public—the public of doctors—had maintained a high standard. Mr. R. F. West, a member of the firm of Baillière, Tindall and Cox, the publishers of the *Medical Press*, read from Arthur Jacob's initial editorial in the first issue in 1839: "A free press is the most powerful means in existence to elicit truth, to encourage honesty, to drive out folly, and to resist oppression."

Swiney Prize

The Swiney Prize for medical jurisprudence for 1949 has been awarded, on the recommendation of a joint committee of the Royal Society of Arts and the Royal College of Physicians of London, to Professor John Glaister, for his work *Medical Jurisprudence and Toxicology*. This is the second occasion on which Professor Glaister has received the Swiney Prize, it having been awarded jointly to him and Professor J. C. Brash in 1939 for their book *Medico-Legal Aspects of the Ruxton Case*. The prize, which consists of a £100 silver cup and money to the same amount, is awarded on every fifth anniversary of the testator's death. It is offered alternately for medical and general jurisprudence.

Fellowships and Scholarships in Dentistry

The Nuffield Foundation announces in the advertisement pages of this week's *Journal* that it is prepared to award a number of fellowships and scholarships in dentistry. Full particulars can be obtained from the secretary of the Foundation, 12 and 13, Mecklenburgh Square, London, W.C.1. The closing date for applications for fellowships is March 1 and for scholarships June 30.

National Institute for the Deaf

The annual report for 1948 of the National Institute for the Deaf describes some of the more important activities of the Institute over the past year. A co-ordinated scheme for approaching local authorities under the National Assistance Act has been prepared for the guidance of welfare societies for the deaf, and a new scheme for the emergency training of lip-reading teachers has been launched. The report also records that the incorporation of the Institute has been completed.

Central Council of Physical Recreation

The Central Council of Physical Recreation has started a new quarterly journal called *Physical Recreation*. It will give news of sports, games, and athletics, and information about holidays and meetings. The journal costs 1s. and is obtainable from the C.C.P.R., at 6, Bedford Square, London, W.C.1.

Wills

Dr. Samuel Walton Wheaton, a former medical officer of the Ministry of Health and assessor to the Miners' Welfare Committee, left £52,569. Dr. William Austin Robb, pathologist to the Royal Devon and Exeter Hospital, left £25,045. Dr. Percy Glyn Savours, Williams, of Exmouth, left £26,686; and Dr. Christopher Richard Kempster, of Great Portland Street, W.1, £6,846.

COMING EVENTS

Symposium on Parasitic Infections

The New York Academy of Medicine will hold a symposium on the biology, metabolism, immunity, diagnosis, and treatment of the more common human parasitic infections on March 15 and 16. Information may be obtained from the Secretary of the Academy, 2 East 103 Street, New York, 29.

Pathology Congress: Date Changed

The date of the 5th International Congress of Comparative Pathology at Istanbul has been changed to April 22-29. Delegates and members who intend to take part should notify Professor N. R. Belger, Taksin, Siraserviler 75/3, Istanbul, Turkey, or the honorary secretary, British National Committee, immediately. A boat will leave Marseilles on April 15 and arrive at Istanbul on April 21. On the return journey a boat departs on April 29 and arrives at Marseilles on May 4. Members who wish to travel by air will leave London on April 19, arriving at Istanbul on April 20. They will reach London after the Congress on May 1. Full particulars of itineraries and hotel accommodation can be obtained from Messrs. Thos. Cook and Son, Ltd., Berkeley Street, London, W.1. As accommodation in Istanbul is limited, early booking is advisable.

SOCIETIES AND LECTURES

Monday

LONDON UNIVERSITY.—At Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E., Feb. 7, 4.30 p.m. "*The Transmission of Nervous Activity*," by Dr. G. L. Brown.
LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, London, W.C., Feb. 7, 4.45 p.m. "*The Ultracentrifuge and Electrophoresis Apparatus in Protein Research*," by Dr. P. Johnson, Ph.D.

Tuesday

CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, 47, Queen's Gate Terrace, London, S.W., Feb. 8, 7 for 7.30 p.m. Discussion: "*Insidious Onset of Grave Disease*." To be opened by Dr. Desmond MacManus.
INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Feb. 8, 5 p.m. "*Histopathology of the Skin*," by Dr. I. Muende.
INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Feb. 8, 11 a.m. "*Bacterial (Non-gonococcal) and Spirochaetal Urethritis*," by Dr. A. H. Harkness.
LONDON UNIVERSITY.—At London School of Hygiene and Tropical Medicine, Keppel Street, W.C., Feb. 8, 5.15 p.m. "*Virus Research and the Virus Problem*," by Dr. Pierre Léprie (Institut Pasteur, Paris).
LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, London, W.C., Feb. 8, 5.15 p.m. "*The Integration of the Bodily Functions*," by Dr. E. A. Underwood.

Wednesday

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Feb. 9, 11 a.m. "*Bacterial Urethritis-cervicitis and Inclusion Blepharorrhoea*," by Dr. A. H. Harkness.
ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, 242, St. Vincent Street, Glasgow.—Feb. 9, 5 p.m. "*Researches into Intrathoracic Tuberculosis in Childhood*," James Watson Prize Lecture by Dr. J. H. Hutchison.
ROYAL SANITARY INSTITUTE.—At 90, Buckingham Palace Road, London, S.W., Feb. 9, 2.30 p.m. Discussion: "*The Purification and Control of Swimming-bath Water*," to be opened by Mr. R. C. Hoather, Ph.D., and Dr. G. J. Laws.

Thursday

EDINBURGH ROYAL INFIRMARY.—Feb. 10, 5 p.m. "*Diet and Dental Health*" Honyman Gillespie Lecture by Dr. A. P. Meiklejohn.
LUNTERIAN SOCIETY.—At Grosvenor House, Park Lane, London, W., Feb. 10 Annual dinner.
INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Feb. 10, 5 p.m. "*Physio- and Electro-therapy*," by Dr. R. T. Brain.
INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330-2, Gray's Inn Road, London, W.C.—Feb. 10, 11.15 a.m. "*The Physical Principles of Audiometry and Hearing-aids, I*," by Dr. T. S. Littler.
INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Feb. 10, 11 a.m. "*Reiter's Syndrome*," by Dr. A. H. Harkness.
LONDON UNIVERSITY.—At Large Lecture Theatre, St. George's Hospital Medical School, Hyde Park Corner, London, S.W., Feb. 10, 4.30 p.m. Lecture-demonstration: "*Neurology*."
LONDON UNIVERSITY.—At Westminster Medical School, Horseferry Road, London, S.W., Feb. 10, 5 p.m. "*Surgical Aspects of Meningitis*" Special University Lecture by Sir Hugh Cairns.
ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE.—At College of Art and Technology, The Newarke, Leicester, Feb. 10, 7.30 p.m. "*The Catarrhal Child*," by Dr. J. Browning Alexander.

Friday

ROYAL MEDICAL SOCIETY, 7, Melbourn Place, Edinburgh.—Feb. 11 8 p.m. "*National Intelligence*," by Mr. J. H. Brown.
WEST KENT MEDICO-CHIRURGICAL SOCIETY.—At Miller Hospital, Greenwich High Road, London, S.E., Feb. 11, 8.30 p.m. "*The Prostatic Patient*," by Mr. J. Gabe.
LONDON CHEST HOSPITAL, Victoria Park, E.—Feb. 11, 5 p.m. "*Pathology of Pneumocystosis*," by Dr. K. F. W. Hinson.
LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, London, W.C., Feb. 11, 5.15 p.m. "*Parasympathomimetic and Parasympatholytic Drugs*," by Dr. F. Bergel, Ph.D.

Saturday

PHYSICAL SOCIETY: COLOUR GROUP.—At B.M.A. House, Tavistock Square, London, W.C., Feb. 12, 2.30 p.m. 44th Science Meeting of the Group, jointly with British Psychological Society Discussion: "*Techniques and Methods of Interpretation of Experiments in Colour as Carried Out by Physicists, Physiologists, and Psychologists*." To be introduced by Mr. R. C. Oldfield, M.A. Drs. R. W. Pickford Ph.D., W. S. Stiles, D.Sc., L. C. Thompson Ph.D., and W. D. Wright, D.Sc.
BIOCHEMICAL SOCIETY.—At Westminster Hospital Medical School, 17, Horseferry Road, London, S.W., Feb. 12, 11 a.m. 273rd meeting. Symposium: "*Biochemical Aspects of Genes*."

APPOINTMENTS

EVANS, T. P., M.R.C.S., L.R.C.P., D.P.H., Divisional School Medical Officer, Amersham and Chesham Divisional Education Executive Bucks.
HARVEY, F. C. R., M.D., D.P.H., Medical Officer of Health for District No 9 (including Aberavenny Borough and Rural areas), Welsh Board of Health (Not Dr. F. C. B. Harvey as previously announced).
NEWMAN, C. T., M.R.C.S., L.R.C.P., D.O.M.S., Assistant Medical Officer, Paddington, British Railways, Western Region.
READ, R. A., M.B., Ch.B., D.P.H., Assistant Administrative Medical Officer, Scottish North Regional Hospital Board.
SILVERTON, M. I., M.R.C.S., L.R.C.P., D.P.H., Medical Officer of Health, Battle Rural District and Borough of Rye, Sussex (Corrected announcement).

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Christie.—On Jan. 24, 1949, at Radcliffe Infirmary, Oxford, to Hilary and Alastair Christie, a son.
Hall.—On Jan. 25, 1949, to Mairi (née Parkin), wife of Dr. Derek Hall of Dover, a daughter.
Ogilvie.—On Jan. 7, 1949, to Joan (née Arnott), wife of Dr. A. C. Ogilvie a daughter—Carol Anne.

MARRIAGES

Fisher.—On Jan. 22, 1949, at St. Mary's, Bryanston Square, London, W., Alfred George Timbrell Fisher, M.C., F.R.C.S., F.A.C.S., of 59 Montagu Square, London, W., to Edith Frances Clive, of Birlingham Manor, near Pershore, Worcestershire.
Goodman.—On Dec. 16, 1948, Cyril J. Goodman to Ruth Sabel, M.B. Ch.B., Tidways, Creechsea, near Burnham-on-Crouch, Essex.

DEATHS

Beachcroft.—On Jan. 24, 1949, at Bercsford, South Hayling, Hants, Francis Seward Beachcroft, M.R.C.S., L.R.C.P., aged 80.
Borland.—On Jan. 12, 1949, Hugh Howie Borland, M.B., Ch.B., D.P.H., of Dennistoun, Glasgow, aged 91.
Burlton.—On Jan. 22, 1949, at Petersfield, Arthur Hyde Burlton, L.R.C.P. & Ed. Lieutenant-Colonel R.A.M.C., retired, aged 95.
Connal.—On Jan. 26, 1949, at 626 King Street, Aberdeen, Andrew Connal, O.B.E., M.D., D.P.H., D.T.M. & H. medical officer to the Aberdeen Training Centre formerly Director of the Medical Research Institute Lagos, Nigeria.
Dodds.—On Jan. 26, 1949, at Middlesex Hospital, London, W., Robert Leslie Dodds, F.R.C.S., F.R.C.O.G., aged 50.
Erskine.—On Jan. 21, 1949, at a Harrogate nursing home, Alexander McConneil Erskine, M.D., D.P.H., of Goole, Yorks.
Fenn.—On Jan. 23, 1949, at Conchillas, Greenway Lane, Bath, Albert Gershon Fenn, M.B., Ch.B.
Jones.—On Jan. 24, 1949, at sea, Crawford Maxwell Jones, M.B., Ch.B., Colonial Medical Service.
Kelly.—On Jan. 29, 1949, at 36 St. Mary's Mansions, London, W., Thomas Bernard Kelly, D.S.O., F.R.C.S. Ed., Colonel I.M.S., retired.
Martin.—On Jan. 26, 1949, Charles de Carteret Martin, M.D., of Manor Cottage, Yateley, Hants, Colonel, late I.M.S.
Mullinder.—On Dec. 9, 1948, in New Zealand, Edward Keith Mullinder, M.B., Ch.B., D.P.M.
Richards.—On Jan. 22, 1949, at Island of Grenada, B.W.I., Hugh Augustine Richards, M.R.C.S., L.R.C.P., D.A., of Epsom, Consulting Anaesthetist to King's College Hospital.
Rumsey.—On Jan. 24, 1949, Cecil Frank Rumsey, M.R.C.S., L.R.C.P., of Ipswich formerly of Cambridge.
Spurrell.—On Jan. 26, 1949, at "Fro Wen," Carmarthen, Charles Spurrell, F.R.C.S., aged 82.
Thomas.—On Jan. 22, 1949, at Winterton, Norfolk, David Cyril Thomas, M.R.C.S., L.R.C.P., aged 49.
Twigg.—On Jan. 23, 1949, at Hartington, Buxton, Derbyshire, Donald Sargenson Twigg, M.R.C.S., L.R.C.P.
Willans.—On Jan. 27, 1949, at West Newton House, King's Lynn, Norfolk, Sir Frederic Jeune Willans, K.C.V.O., M.R.C.S., L.R.C.P., Surgeon Apothecary to H.M. the King's Household at Sandringham.

AN ORAL TREATMENT FOR FILARIASIS

'Banocide,' a new organic compound free from metallic elements, is markedly active against filariæ, particularly *Wuchereria bancrofti* and *Onchocerca volvulus*, when administered orally. It is particularly effective in dealing with microfilariæ, and, even in moderate dosage, causes their rapid disappearance from the blood stream. As shown by animal experiments, the toxicity of the compound is low. Its stability is unaffected in hot climates. 'Banocide' is issued as compressed products of 50 mgm. in containers of 20, 100, 1000 and 5000.

INTRODUCING A SAFE AND EFFECTIVE SEDATIVE
AND HYPNOTIC FOR REPEATED ADMINISTRATION

from the Laboratory of

T. & H. SMITH LTD.

TABELLÆ SEDATIVÆ

R. Tab. Sedativ. (Smith)

These Tablets present a new combination, providing the well-tried sedative and hypnotic property of Phenobarbitone enhanced by analgesic and antispasmodic action of Codeine.

INDICATIONS: Insomnia, neuralgia, cardiac neurosis, angina, bronchial and cardiac asthma, painful cough, whooping cough, causalgia, dysmenorrhoea, epilepsy, hysteria, migraine, mental disease, chorea, pruritus, in many other conditions where a reliable combination of hypnotic and analgesic is required.

EACH TABLET CONTAINS PHENOBARBITONE $\frac{1}{2}$ GRAIN, CODEINE PHOSPHATE $\frac{1}{4}$ GRAIN, WHICH GUARANTEES AN IDEAL RATE DOSAGE AND CONVENIENCE OF ADMINISTRATION.

MAY BE DISPENSED ONLY ON PHYSICIAN'S PRESCRIPTION

Physician's Sample free
on receipt of signed
order.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Diphtheria Immunization

Q.—From what age is T.A.F. the better immunizing agent?

A.—When the Schick test is performed on older children or on adults a skin response to the control inactivated material occurs in a proportion of cases, causing the so-called pseudo-reaction. This indicates that the individual has become sensitized to some protein fraction in the diphtheria toxoid, and the injection of a full dose of toxoid into such a person will usually be followed by a severe local and sometimes a systemic reaction. This sensitivity to diphtheria toxoid may also be elicited by a small subcutaneous injection of diluted toxoid—the so-called Moloney test. It is therefore advisable that the Schick and the Moloney tests be carried out in adults before any diphtheria prophylactic is given. Among children the proportion of pseudo-reactors is likely to be small, and a preliminary test for susceptibility is not usually carried out; but because T.A.F. is less likely to cause reaction than A.P.T. its use is recommended for school-children of 8 years and upwards who are receiving a booster dose after primary immunization in infancy. This booster dose is effective in a remarkably small dosage, and 0.2 ml. of T.A.F. should be enough to stimulate a good antibody response.

Indications for Nikethamide

Q.—Could you tell me the indications for nikethamide? Apart from its use in shock therapy and in certain poisonings, has it any place in the treatment of acute heart failure, especially in the elderly with chronic bronchitis, of chronic myocarditis, or of coronary sclerosis?

A.—Nikethamide, or pyridine- β -carboxylic acid diethylamide, acts mainly on the central nervous system, increasing the rate and depth of respiration and producing peripheral vasoconstriction. The analeptic action is useful in combating acute respiratory depression from anaesthetics, alcohol, hypnotics, and toxic gases. The drug is of no value in shock unless this is primarily associated with respiratory depression, nor is there any evidence in man that it consistently produces a rise in blood pressure or promotes increased coronary flow. Nikethamide has been used as a cardiac stimulant, though with doubtful effect in most cases. The relief of respiratory distress that it may produce in some cases of cardiac disease results from its effect on the respiratory system. There is no justification for the use of nikethamide in chronic myocarditis, coronary disease, or angina. It may, however, be of some value in the treatment of acute circulatory failure in pneumonia or chronic bronchitis because of its action on peripheral vascular tone. It is unlikely to be of use in acute heart failure due primarily to a cardiac defect.

Cleft Lip

Q.—What age is most suitable for a repair operation for cleft lip? The case I have in mind is not accompanied by any other defect such as cleft palate.

A.—The question of age is not so important as the clinical condition, but as a general rule, provided the child is 10 lb. (4,536 g.) and is steadily gaining in weight, and its haemoglobin is 80%, the operation should not be deferred. Generally speaking, this means about the fifth or sixth week.

Nematodes and Pulmonary Lesions

Q.—Could bronchiectasis or bronchitis be associated with the presence of nematodes in a chronic case of infestation?

A.—It is only during their relatively brief migration as larvae that certain nematodes cause pulmonary lesions in the human host. The larval forms burrowing in the intestinal wall are

carried by the blood stream and are distributed in the lung capillaries, usually at the periphery, producing marked consolidation of the alveoli rather than bronchitis or bronchiectasis. The larvae then migrate to the bronchioles and from there to the trachea and larynx, but there is no evidence that they cause any great pathological changes during this part of their migration. The changes in the bronchi are thus probably insignificant in comparison with those in the lung. The trauma produced might result in symptoms which persist long after the larvae have left the lung and developed into adults in the gut. This is not usual, however, and in roundworm (*Ascaris*) infections the association of adult worms in the gut, as evidenced by the presence of eggs in the faeces, with pulmonary symptoms is usually ascribed to reinfection.

Skin Eruption Associated with Menstruation

Q.—Since her first confinement five years ago a woman aged 28 has suffered from an erythematous-papular eruption on both temples, starting seven days before each period, reaching its maximum during the period, and fading during the next seven days. It is absent only during pregnancy. Progesterone, "benadryl," and non-specific desensitization have failed to cure it. What are the aetiology, treatment, and prognosis?

A.—The information given about the character of the lesions and the menstrual history is inadequate. The lesions are probably in the nature of acne frontalis or possibly an ordinary acne or rosacea. Any pelvic abnormality or infection should be excluded: it is presumed that the patient does not take any drugs over this period for pain or other symptoms. Locally, ung. hydrarg. ammon. aquosum, or a 2% sulphur and salicylic acid ointment, or fractional doses of unfiltered x rays, should help. Any internal treatment must rest upon a better appraisal of the background.

Winter Resorts for Respiratory Infections

Q.—Can you help me to advise a patient suffering from chronic fibroid tuberculosis of the lungs about a health resort in Southern England where he can spend the winter months? Also, are the Canary Islands or Scilly Isles suitable?

A.—A patient suffering from chronic fibroid tuberculosis often derives benefit from wintering at one of the health resorts along the south coast of England, particularly if it is sheltered from high winds and is not too hilly. There are a number of resorts that fulfil these conditions, and the particular one chosen usually depends on the temperament of the patient. The Canary Islands have a suitable and pleasant winter climate, but difficulties may arise in obtaining residence for a patient with active tuberculosis. The Scilly Isles usually have periods of high winds during the winter months, which can cause some discomfort to a patient suffering from chronic respiratory infection.

Subacute Combined Degeneration

Q.—It is well known that the signs of subacute combined degeneration of the cord (S.C.D.) may be present before the blood changes of pernicious anaemia occur; also that the accompanying disorder of gastric secretion usually begins with achlorhydria and only later proceeds to deficient secretion of pepsin and intrinsic factor. (a) Is it possible to suffer from S.C.D. in the absence of achlorhydria? (b) Could the absence of intrinsic factor in such a case be demonstrated by Castle's method? (c) Is marrow puncture of help in a case of S.C.D. with a normal peripheral blood?

A.—(a) Histamine-fast achlorhydria is such a constant feature of S.C.D. that on the few occasions when free HCl in the gastric juice has been reported the diagnosis may be open to question. A case of macrocytic anaemia associated with neurological signs and symptoms, together with the finding of free HCl on gastric analysis, was reported by Harvey and Murphy (*Arch. intern. Med.*, 1933, 6, 1393), but the patient had duodenal and upper intestinal diverticula. Other cases may be of sprue or examples of the nutritional macrocytic anaemia group associated with neuritis. These cannot be regarded as S.C.D. in the usually accepted sense.

(b) The writer is unaware of the demonstration of intrinsic factor in any such case. As it is unknown whether the hypo-

thetical "S.C.D. factor" is distinct from the anaemia factor, the question of expecting the latter to be demonstrable would depend on whether or not one believes in a separate "neuropoietic factor."

(c) While in untreated cases of S.C.D. with slight anaemia the bone marrow may contain megaloblasts, more often at this stage the marrow picture is rather equivocal. One would not expect any pathological change in the marrow of a patient with a strictly "normal blood picture."

Stilboestrol and Testicular Swelling

Q.—A man of 75, with multiple deposits of prostatic carcinoma in bones, has been treated with very large doses of stilboestrol. The deposits are disappearing, but the only testicle has become acutely tender and a little swollen. Is this due to the treatment?

A.—The biological effect of stilboestrol is to produce involution of the testes and physiological castration. This is usually manifested by a shrinkage of the testicles and a disappearance of libido. It is therefore most unlikely that the swelling and tenderness of the testicle are due to stilboestrol therapy. It may be an infective epididymo-orchitis.

Persistent Symptoms after Brucella Infection

Q.—What is the best treatment for a case of chronic Malta fever of seven years' duration? The symptoms now present are recurrent "neuritic" pains in the limbs and extreme lassitude; the only sign is an intermittent evening rise of temperature to 99°–100° F. (37.2°–37.8° C.).

A.—Seven years is an unusual time for "Malta fever" to last, although at least one case has been reported where the infection remained active for eight years. It would thus be wise to exclude all other causes of fever before accepting the present symptoms as due to the brucella infection. Residual infections of the gall-bladder and prostate with *Brucella melitensis* may be responsible for an unduly prolonged course, and these organs should be re-examined with this in mind. Cholecystectomy may be indicated. Brucellin—a suspension of the nucleoprotein of the organism—has been used with some success (I. P. Huddleston, *Brucella Infections in Animals and Man*, New York, Commonwealth Fund, 1944). Recently there have been encouraging reports of the simultaneous administration of streptomycin and sulphadiazine.

Spasmodic Cramps

—I am 77 and have had rheumatoid arthritis in the hands for four years. Following an attack of pneumonia ear ago, the rheumatic condition flared up, and since then have been confined to bed with attacks of severe cramp in the knees and wrists lasting four or five seconds. The cramp comes on with the first movement of the limbs on awaking from sleep about 1 a.m., and recurs five or six times. The knees are painful on movement and on pressure, making walking impossible. The swelling of the knees has gone down considerably but the cramp persists. I had a course of gold injections two years ago. My erythrocyte sedimentation rate is 4 mm. in 1 hour and leucocyte count 10,000 per c.mm. What treatment would you suggest for the cramp, and what causes it?

A.—The data in this case are insufficient for a definite opinion to be formed. The erythrocyte sedimentation rate of 4 mm. in 1 hour does not suggest a rheumatic condition but that the arthritis may be of a different nature, though the association of a type of myositis with joint symptoms is now recognized. Cramp of the kind described may be due to a calcium deficiency, and the calcium metabolism should be investigated, especially the calcium-phosphorus ratio in the blood and urine. A complete clinical examination is called for, including the nervous system. If any line of treatment which this might indicate proves unsuccessful a course of calcium with vitamin D by injection daily for a week or two, and by mouth as well for a long period, should be tried, and in addition 10 gr. (0.65 g.) of calcium aspirin given at bedtime and repeated once in the night.

NOTES AND COMMENTS

Home-cured Tobacco.—The Rev. HUGH CUTHBERTSON, president of the National Amateur Tobacco Growers' Association, writes: Your reply on the subject of amblyopia and home-cured tobacco ("Any Questions?" Jan. 22 p. 163) vindicates the position I have always taken on the importance of a fermentative process. This is recommended in the literature of the National Amateur Tobacco Growers' Association, as also the removal or crushing of the mid-rib. Plans were made last year to provide facilities for bulk fermentation under professional guidance, but had to be abandoned for the time being owing to the intervention of Customs and Excise. This does not mean that small-scale methods such as can be carried out in the home are not adequate or that there is any justification in the wording of your article for the misleading headlines in the national Press on the "danger" of home-grown. Some months ago a charge of high nicotine content in home-grown leaf was made in the Press, but my challenge to produce evidence was never met. You will realize, as we do, that some interests are prejudiced against the reputation of garden grown, indeed of any European, leaf. In point of fact, most imported tobacco sold in this country does not, I believe, go through any process of fermentation except such as naturally occurs in bond. We would like further information on this, and also whether the data you give on amblyopia on the Continent refer only to smoking or include the chewing of tobacco. A leaflet is now in the printer's hands on the subject of fermentation of amateur tobacco, a copy of which we should be pleased to send to correspondents with any other information they require. The association would give what co-operation and assistance it can in research on the subject.

Lobeline and Asphyxia.—Dr. HECTOR MACLEAN (Lockerbie, Dumfriesshire) writes: In "Any Questions?" (Dec. 11, 1948, p. 1047) on the subject of lobeline in asphyxia your expert states that the real need is for oxygen. Now if the infant can be made to breath vigorously for a few minutes, and only if, it will get all the oxygen it can be doing with. If you give lobeline by intrapulmonary injection, a few valuable seconds are saved while the lobeline gets to the respiratory centre. I once came on a hill-farmer, one of whose lambs had choked on a bottle of milk. The lamb's mucous membranes were black; it was obviously gasping its last, and there and then respirations ceased. The heart beat became feeble and the lamb was to be abandoned. I blew up its lungs with my mouth in the time-honoured fashion, and the heart beat improved, but respirations did not occur. So I gave 1 ml. of lobeline intrapulmonarily, and in "two shakes" the lamb was panting vigorously. It made an uninterrupted recovery and eventually sold for a good price. On another occasion, during "pentothal" anaesthesia we got an alarming spasm of the glottis, and by the time the syringe was loaded up the patient was almost "finis." A few seconds after intrapulmonary injection the patient was breathing furiously, and pulse and colour were rapidly restored.

Pressure-cooker as Sterilizer.—Mr. G. H. DONALD, B.Sc., of Good Housekeeping Institute, writes: I would like to correct a wrong impression imparted in the answer given on this subject ("Any Questions?" Jan. 15, p. 121). We have tested most of the pressure cookers on the market and in all cases the air is expelled before the raising of the pressure. In fact, with pressure pans the steady stream of steam is the indication to the housewife that the gauge must be closed down for the raising of the pressure. On the other hand it is quite possible—and is often done—to start the cooking in water that is already boiling. It seems to me, too, that the dressings to be sterilized could be placed in an enamel bowl. In the latter case the steam would come into contact with them without moistening them with the water itself.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY FEBRUARY 5 1949

REMUNERATION: THE PRESENT POSITION *

ADDRESS BY DR. CHARLES HILL TO METROPOLITAN COUNTIES BRANCH

A meeting of the Metropolitan Counties Branch was held on an. 27 for an address by Dr. Charles Hill, Secretary of the Association. Mr. A. M. A. Moore presided over an audience which filled the Great Hall of B.M.A. House.

Dr. Hill began by saying that certain issues in the field of terms of service, particularly the issue of remuneration, dominated the scene to-day. Although he proposed to deal principally with the general practitioner position, he might say at the outset that in the consultant sphere meetings were taking place between the Joint Committee for Consultants under Sir Lionel Whitby's chairmanship and the Ministry of Health. The Ministry in what for the moment was a confidential document had given its interpretation of the Spens specialist report on remuneration, and the Joint Committee was at the moment not negotiating but advising the Ministry on such changes in the proposals as seemed desirable if they were to be acceptable to the profession. When the document was published, as was shortly to be expected, it would be examined by the profession through its various organizations, and the profession, in the consultant and specialist field in this instance, would express its views.

This procedure rendered inevitable the extension of the provisional terms, at present due to terminate on March 31, for a further three months. When the terms were finally agreed they would be retrospective to July 5 of last year. It was expected that the Government's statement of terms would be published in a few weeks' time.

Although the two Spens Reports laid down ranges of remuneration only for general practitioners and consultants, these documents would have their relevance in the public health negotiations. Difficulties had been raised by the associations of local authorities to the opening of negotiations on the Whitley machinery, and the B.M.A. had informed the Ministry that unless such negotiations were opened by the end of February there would be published in the *British Medical Journal* only those advertisements which conformed with the Association's own proposals. It was confidently hoped that the stimulus as applied through the Ministry to the associations of local authorities would result in a speedy opening of negotiations.

General Practice and the Spens Report

Turning to the field of general practice, Dr. Hill reminded the meeting that the Spens Report had been accepted both by the representatives of general practitioners and the Ministry as the basis for future remuneration. He outlined its main recommendations, and concentrated for the purpose of argument on the recommendation that half the profession in general practice between the ages of 40 and 50 should be receiving a net income of £1,300 a year (pre-war money basis) or over, and that 10% should receive a net income of at least £2,000.

In converting 1939 money values into post-war money values, Spens stated that regard should be paid to two factors—one

the changed value of money, and the other such increases in remuneration as had been secured by other professions. He would deal with the subject of betterment later on in his address. At the outset of the Service it was impossible to determine what would be the spread of income between different groups in the profession, but it was possible to attempt to estimate the total sum of money which would be necessary to give effect to the Spens recommendations in the aggregate, leaving the proof of whether Spens had been actually applied to be determined in the light of experience after three or six months.

It was agreed between the Government actuary and the actuary acting for the Association that the Spens recommendations in fact meant that in the aggregate general practitioners before the war were under-remunerated to the extent of £3 million. The aggregate pre-war general practitioner income was calculated by Professor Bradford Hill in preparing the Association evidence for the Spens Committee as £28 million gross. To that sum £3 million was added in order to make good the deficiency stated by Spens to exist, and a further £1 million was added in view of the increase of population since that time. To this total of £32 million had then to be applied a figure for betterment. The Government figure, laid down at the end of 1946, was 20% in respect of net remuneration—that is, remuneration after deduction of practice expenses. The betterment factor laid down by the Government as applicable to practice expenses was 55%. The combination of these two figures, the 20% applying to two-thirds of the total remuneration, in relation to the capitation fee as a whole worked out at 34%, or £10.5 million, bringing the total to £42.5 million.

This was the sum calculated on the assumption that the whole population of this country used the Service. It was agreed, as a matter of guesswork, that at the outset it should be assumed that 95% proposed to use the Service, thus bringing down the figure just stated to about £40.5 million. To this had to be added sums in respect of fees for maternity services—probably £2 million—the sum set aside for the Inducement Fund—at that time £400,000—and a sum representing the Government's contribution to superannuation. Roughly, that would bring the amount to £45 million as the aggregate remuneration for general practitioners according to the Spens recommendations, and on the basis of £28 million as representing the pre-war income.

The Application of Spens

The next step was to find out whether this aggregate sum was being applied, and accordingly, despite the limitations necessarily imposed on a survey taken early in the Service, an attempt had been made to answer that question. Earlier in his address he had taken the figure of £1,300 as representing the net income, on a pre-war basis, for 50% of general practitioners between the ages of 40 and 50. That figure, on the basis of the above calculations, should now be £2,613 gross. In the second example—the 10% who should receive a net income of at least £2,000—the new figure should not be less than £4,020 gross.

It was too early to make a country-wide survey, but a survey had been made in Lancashire, Halifax, Bath, Nottingham.

*This report of a meeting addressed by the Secretary, Dr. Charles Hill, replaces this week the usual commentary that appears under "The Secretary Reports."

Nottinghamshire, and Norfolk. The calculations were based on taking the cheque paid to the individual practitioner for the first quarter, adjusting for the four unpaid days July 1 to 4 (there was some reason to expect that the final payments under National Health Insurance would be made in about a fortnight's time), and multiplying the sum by four. Certain additions had to be made to this figure—the 5% representing the proportion of the central "kitty" kept for further contingencies, and the 9% of the gross remuneration representing contributions for superannuation. To this 14% there remained to be added a figure representing sums received on account of appointments of one kind and another, maternity services, notification of infectious diseases, fees for immunization and vaccination, etc. A conservative estimate might be 6%, bringing the total figure to 20%, being moneys not represented in the quarterly cheque.

In the surveys which had been made, taking the basis that 50% of general practitioners of the given age group should be receiving £2,613 or more, in only one area was the percentage less than this (43%), and in the other areas it was higher than 50%. Again, according to the estimate, 10% should be receiving incomes of not less than £4,020, and the percentage in the areas surveyed varied between 0 and a percentage higher than 10. These surveys had been made before steps had been taken to insist on the 4,000 permitted maximum for the single-handed principal—an important qualification.

In general the position appeared to be that, on the assumption of a betterment of 20%, Spens was for the most part being satisfied in the middle and upper ranges of income. It must be known exactly what the facts were before the size of the problem existing could be judged, and certainly a problem did exist. The first thing to bear in mind was that, even though there might be an overall satisfaction of Spens, there were still individuals and groups in the profession who were suffering considerable hardship at the present time (Applause). While in general terms Spens was being applied in the upper income groups, it was on the margin of application, and in certain areas well below the margin, in some of the lower income groups.

The Problem of Betterment

Dr. Hill went on to point out that if the 20% figure for betterment was too small the whole of these calculations became invalid and would have to be done again on a new assumption. The first problem was that of betterment, not the problem of the overall application of Spens. At the end of 1946 the Government decided on a figure of 20% for net remuneration. A promise was secured that this could be raised under the Whitley machinery as soon as that was established. It was expected that this would be immediately after the appointed day. For the delay the profession was in part responsible, because it had had misgivings concerning certain features of Whitley, notably what seemed to be the possibility that medical remuneration might be subject to review along with that of other groups in the Service; and latterly there had been delay because local authorities had discovered that Spens ranges as applied to public health medical officers would mean similar ranges applied to town clerks, borough surveyors, and the like.

When the Government laid down the figure of 20%, the expert advice was that the cost-of-living figure for the professional classes in 1945 was 145, but the position to-day, judged by the same expert, was that the figure for 1948 was 185. Therefore, unless there was an increase in betterment, in fact there had been a diminution in real value of the income since the figure was first proffered by the Government. It was of paramount importance that the betterment figure should be raised now to something comparable with the real cost-of-living figure of 185. When the right betterment figure had been secured it would be time to recalculate current incomes and to decide whether Spens was really being applied.

Increased Burden of Work

Spens or no Spens, the next problem was the increased burden of work now falling on the profession (Applause). He was not referring now to abuses, but to the overall result of making a free service available to the whole community. If it were true

that the burden of work had greatly increased, could they adhere to the position, while complaining of this increase of work, that a practitioner could satisfactorily look after 4,000 persons on his list? If they deliberately put forward the consideration of an excessive burden of work it automatically raised the issue of the maximum list.

There was one advantage in the Spens method despite its mathematical difficulties. Spens said that the practitioner who had the maximum on his list should have a certain level of income; it did not say that he should have 4,000 or 5,000 on his list, and if there was a reduction in the permitted maximum it followed that there would need to be a corresponding increase in the capitation fee to achieve the Spens level of income. But there was one snag about that. Spens said that the percentage of the profession getting the maximum should be in the region of 10%. If the lowered maximum raised the percentage of the profession enjoying the maximum remuneration level, obviously there was another situation to be considered. But the application of an adequate figure for betterment might well remove this difficulty.

The biggest problem at the moment was that of the practitioner with the average or less-than-average list. Practitioners with lists of moderate size were finding themselves not only hard-hit financially but fully occupied professionally because of the burden of work. Some men had small lists because they deliberately kept them small, preferring to have a small number of patients and to give them increased medical care; possibly some practitioners failed to attract a sufficient number of patients to themselves; others might have small lists because of a superabundance of practitioners in their particular area; and then again there were practitioners in rural areas where, because of sparsity of population and time involved in travelling, there could be no large lists. Rural practitioners had lately received a substantial improvement in their mileage allowance. Indeed, the Association had had one letter of thanks about it—(Laughter)—though the grateful writer added that the concession was not nearly large enough. The Mileage Fund had been increased by rather more than 50%. This had an importance for the urban practitioner because any suggestion that general practitioner remuneration and mileage were two parts of the same fund, and that any increase of mileage payment would have to come out of general remuneration, had been broken down.

Again, there was the problem of the area where the number of doctors was too high. The profession had claimed that the capitation fee system would so influence the distribution of doctors as to make direction and control unnecessary. Nevertheless, this was a poor consolation to a man whose roots were embedded in an area and who found that more doctors were there than could possibly have lists of sufficient size. Somehow or other it must be secured that it was possible for practitioners decently and properly to live with lists of the order of 1,500–2,000. It might be possible to pay to all practitioners an expenses amount designed to meet the situation whereby the practitioner with the smaller list had inevitably a larger ratio of expenses. Another method would be a substantially higher capitation fee for the first 1,000 or 1,500, the average capitation fee for those with the maximum list remaining unaffected. They had condemned the tapering capitation fee, but the problem of remuneration in the light of new experience must be regarded with an open mind.

To sum up, an adequate betterment factor, together with certain other considerations, including the number of doctors in the Service, should result in a larger total sum being made available and a higher average capitation fee; a lower maximum on lists, with the resultant proportionately higher capitation fee, should be considered; by one means or another substantially higher incomes must be secured for those of average and less-than-average lists. These things secured, the Inducement Fund and fixed annual payment arrangements could assume insignificant proportions.

The Amending Bill

Passing from problems of remuneration, Dr. Hill went on to speak of the amending Bill. In May, 1948, the Minister, under some persuasion, promised such a Bill in which certain things

would be dealt with, as, for example, that it would be made impossible for any Minister to introduce a whole-time salaried service by regulation, that a legal commission would be set up for the purpose of dealing with that section of the Act which had to do with partnerships, and there were certain other proposed changes. He also promised that the Association should see the amending Bill before it was introduced. The Association, for its part, had a number of changes to suggest, as, for example, that it should be made possible for a doctor attending his patient privately to prescribe for that patient publicly (Applause). It had been suggested in one quarter that the Association itself should provide resources for a patient to take up this matter in the courts and sue the Minister on his right to have his pharmaceutical and other service out of the public provision. But the words of the Act (Sect. 38 (2)) were very plain: "to enable any person receiving general medical services to obtain . . . drugs and medicines and prescribed appliances if ordered by the medical practitioner rendering those services," and the definition of "general medical services" was "services under the Act." But they were going to press for such an amendment as would make it legal and proper for the patient treated privately to obtain his drugs and appliances within the Service.

Another amendment would concern foreign visitors—the *Argentinian visiting Wales, the American visiting London*—and their supposed right, as apparently obtained at present, to come within the definition (Sect. 1 (1)) of "the people of England and Wales." Yet another point to be secured was a modification of the position so as to obtain for the staffs of non-teaching hospitals the same position in relation to medical membership of hospital management committees as was enjoyed by members of teaching hospital staffs; another involved a grant-in-aid for patients occupying private beds. A number of such changes were being sought in connexion with the less controversial of the terms of service. He had nine points on his list which were being pressed upon the Ministry; but the governing issue was to ensure that the work was of such an amount as could be reasonably and efficiently undertaken, with a remuneration which represented a proper and decent reward for the services rendered (Applause).

A Plea for Unity

"I know it is not easy," Dr. Hill said in conclusion, "for those who do not participate in central discussions and representations to appreciate what is being undertaken on their behalf. I urge the profession, glorious though it might be to indulge in highly coloured and emotional rhetoric on this subject, to believe that those who are handling these problems at the centre are doing their utmost in immensely difficult circumstances. One does not expect the profession, when any concession is won, to make any profound or widespread expression of appreciation, and, on the whole, I think they are wise, because it might put wrong ideas into the heads of those who are undertaking the negotiations. But it is only right that there should be a proper appreciation of the work done on behalf of the profession. We cannot claim that it does not justify criticism, but I do hope that the profession will realize that the one paramount need at the present time is sustained unity in its ranks. Let us criticize and curse each other—and, of course, curses can be most appropriately directed to this establishment—but let us not forget that in a crisis the profession did stand together, and I hope that whatever divisions and discontents there may be we shall hold together still, for it may not be so very long before a further exercise in cohesive action will be needed" (Applause).

Questions Answered

The first question from the audience was, "Why does not the B.M.A. demand a capitation fee of 30s. and back the demand with a threat of resignation within three months? Why be tied to Spens?"

Dr. Hill replied that Spens had been accepted, and it was in the interests of the profession to continue to accept it with an appropriate betterment factor applied. The Government was tied to Spens. With a proper betterment factor and adjust-

ments to meet the problems of the small-list practitioner the question of remuneration could be solved. It was well to remember that Spens laid down levels of remuneration to be observed however many doctors entered general practice. *Even though maximum lists were reduced, Spens remained untouched.* Should they demand a capitation fee of 30s.? It might be that the various additions and adjustments would bring the capitation fee up to something in that region. But they could not bluntly state a figure for which they could not produce arguments and then expect the profession to withdraw on the basis of that figure. Dr. Hill reminded the gathering that there were many men in thickly populated urban areas whose incomes were in a satisfactory condition as a result of this Service.

Asked whether any increase obtained would be retrospective to July 5, 1948, Dr. Hill said he could not answer that, but there was a strong case for a retrospective arrangement of that kind.

Asked whether there would be a quarterly or annual review of the betterment factor, Dr. Hill said they would reserve their rights to raise and submit to arbitration the cost-of-living position in relation to betterment at any time in the future. Nevertheless, he hoped some stability would be secured for a reasonable period by means of the betterment factor.

Points from replies to other questions were as follows:

Representations were being made to the Ministry concerning the position and emoluments of practitioners of the registrar class.

Why was a means test required in the allocation of basic salary? It was required in order that the higher rate of remuneration—for that was what basic salary meant in the case of those with lists of less than 2,300—should be paid only where it was justified. It was felt that a man who demanded this higher rate of remuneration from the local pool should prove justification.

Why not abandon the capitation fee in favour of payment for service rendered? The Government might well be brought to agree to a fee for each item of service, but it would insist on a statement in advance of its commitments, and that would mean a limited pool for distribution. Once there was such a pool it would be open to occasional abuses, and "one bad boy in the profession can arouse resentment out of all proportion to his badness."

The surveys did not apply to London, because areas had to be chosen where the problem of duplication of entrants on executive council lists was small. But final conclusions could only be drawn from a country-wide survey.

Asked what means could be taken to prevent abuses causing the practitioner unnecessary work, Dr. Hill said that a good deal of the increased volume of work was naturally to be expected as a result of the extension of the Service. This included the composite family consultation. If the practitioner was properly paid for the job and had sufficient time to do it, it was not altogether an unhealthy thing for him to be brought into contact with those who were not so ill or even those who were completely well. The essence of the answer was satisfactory terms of service.

The meeting closed with the moving, by Dr. R. W. Cockshut, of a vote of thanks to Dr. Hill, which was enthusiastically carried.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), WallSEND.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

Dangerous Drugs Acts: Withdrawal of Authority

The Home Office announces that Dr. John Millar Matthew (Cheltenham) is no longer authorized to be in possession of or to prescribe those drugs to which the Dangerous Drugs Regulations apply.

National Health Service

STANDING ADVISORY COMMITTEES

A Statutory Order made by the Minister of Health and coming into effect on Feb. 1 constitutes the following nine Standing Advisory Committees which will advise the Minister and the Central Health Services Council on those parts of the National Health Service which come within their fields: Medical; Dental; Pharmaceutical; Ophthalmic; Nursing; Maternity and Midwifery; Tuberculosis; Mental Health; Cancer and Radiotherapy.

The names of the members of the Medical Advisory Committee are printed below, with their terms of office. The names of the members of the other Advisory Committees will be published in a future issue of the *Supplement*.

(a) *Members Appointed by the Minister after Consultation with the Central Health Services Council.*—Dr. Janet Aitken, physician (until March 31, 1950); Professor William George Barnard, pathologist, member of St. Thomas's Hospital Board of Governors (until March 31, 1950); Mr. Aleck William Bourne, obstetrician and gynaecologist (until March 31, 1950); Dr. James Alexander Brown, general practitioner, member of Birmingham Regional Hospital Board (until March 31, 1952); Sir Ernest Rock Carling, surgeon (until March 31, 1952); Professor Sir Henry Cohen, physician, member of Liverpool Regional Hospital Board and Board of Governors (until March 31, 1952); Dr. Harry Guy Dain, Chairman of Council of the British Medical Association (while Chairman of Council of the British Medical Association); Sir W. Allen Daley, Chairman of the Council of the Society of Medical Officers of Health (while Chairman of the Council of the Society of Medical Officers of Health); Sir William Gilliatt, President of the Royal College of Obstetricians and Gynaecologists (while President of the Royal College of Obstetricians and Gynaecologists); Dr. Edward Andrew Gregg, general practitioner, member of County of London Executive Council (until March 31, 1951); Dr. Wilfred Vivian Howells, general practitioner, member of Swansea Executive Council (until March 31, 1950); Dr. Horace Joules, physician and medical director, member of N.W. Metropolitan Regional Hospital Board and of Hammersmith, etc., Board of Governors (until March 31, 1951); Professor Aubrey Julian Lewis, psychiatrist, member of Bethlem and Maudsley Hospital Board of Governors (until March 31, 1952); Dr. William Gordon Masefield, psychiatrist, member of S.E. Metropolitan Regional Hospital Board and of Bethlem and Maudsley Board of Governors (until March 31, 1951); Lord Moran, President of the Royal College of Physicians of London (while President of the Royal College of Physicians); Dr. William Norman Pickles, general practitioner, member of Yorkshire North Riding Executive Council (until March 31, 1951); Professor Sir Harry Platt, orthopaedic surgeon, member of Manchester Regional Hospital Board and Board of Governors (until March 31, 1951); Professor James Calvert Spence, paediatrician, member of Newcastle Board of Governors (until March 31, 1952); Dr. Clement Willoughby Walker, general practitioner, member of Cambridge Executive Council (until March 31, 1950); Lord Webb-Johnson, President of the Royal College of Surgeons of England (while President of the Royal College of Surgeons).

(b) *Members Appointed by the Minister after Consultation with Representative Organizations.*—Dr. Walter Russell Brain, physician and neurologist, member of London Hospital and National Hospitals Boards of Governors (until March 31, 1953); Mr. Somerville Hastings, M.P., surgeon, member of North-East Metropolitan R.H.B. and Boards of Governors of Hammersmith and Middlesex Hospitals (until March 31, 1951); Mr. Robert Leech Newell, surgeon, member of Manchester R.H.B. and Board of Governors (until March 31, 1952); Dr. Wyndham Parker, County Medical Officer of Health, Worcestershire (until March 31, 1951); Dr. James Ralston Kennedy Paterson, radiologist (until March 31, 1953); Dr. William Gilchrist Patterson, Senior Administrative Medical Officer, Newcastle R.H.B. (until March 31, 1952). Secretary: Mr D. Emery (Tel.: Whitehall 4300, Extension 172).

NORTHERN IRELAND GUILD

The Northern Ireland General Medical Practitioners' Guild has issued a questionnaire to every general practitioner in Northern Ireland inviting answers to a number of points in connexion with remuneration and terms and conditions of service. The primary object of the Guild is to secure satisfactory terms and conditions of service for general practitioners, working in conjunction with or through the Northern Ireland Branch of the B.M.A. and the Negotiating Committee set up to discuss terms and conditions of service with the Government.

In the questionnaire practitioners are invited *inter alia* to say whether or not they are in favour of: increased capitation fee; increased mileage allowance; immediate payment of compensation; sliding scale of remuneration; lower ceiling (combined with increased capitation fee); a fully salaried medical service; immediate limitation of the number of general practitioners in Northern Ireland taking part in the new Health Service; free locum during illness; payment of maternity fees for nursing-home cases; continuation of the right of the general practitioner to attend his patients in cottage and district hospitals; better pensions for doctors' widows; that the Guild become the autonomous General Practitioners' Branch of the B.M.A.; mass withdrawal of service from the Health Scheme, if required; the necessary alteration being made so that benefits of a trade union could be made available to the members of our profession.

RESTRICTIVE COVENANTS

The Ministry of Health suggests that executive councils, when sending Forms E.C. 16 to applicants for vacancies, should ask applicants whether they are subject to any "disabling condition" such as an agreement with a practitioner which might preclude them from undertaking general practice in the area where they are applying for admission to the medical list. If there is such a condition, the Medical Practices Committee should be informed when the applications and supporting particulars are sent to it.

N.H.I. FINAL SETTLEMENT

The Central Practitioners Fund (England) for the period Jan. 1 to July 4, 1948, has been determined at £7,770,801. The Minister has accepted the recommendations made by the Medical Distribution Committee on the proportions in which this sum should be distributed among the areas of the former Insurance Committees. Payments should have been made by Jan. 31.

HEARD AT HEADQUARTERS

Worried Alderman

A correspondent draws our attention to the remarks of Alderman J. A. Mason reported in the *Worthing Herald* of Jan. 22. The doctors "are not doing so badly," said the alderman. "A doctor on the present basis is to receive from £500 to £5,000 per annum, and in addition he will have his private practice, which is very considerable in some cases." But where are all these private patients? Mr. John Edwards, Parliamentary Secretary to the Ministry of Health, speaking in Parliament on the same day said that about 95-98% of the population are in the scheme. We can only conclude that private practice has become as difficult to discern as the alderman's line of reasoning, and we cannot guess where he learnt that doctors "are not doing so badly"—a view apparently not shared higher up. Mr. Messer, chairman of the Central Health Services Council, in the same Parliamentary debate said that "great hardship is being experienced by many general practitioners at present . . . clearly everybody knows that the situation cannot remain as it is." Mr. Mason was moving a resolution that his council should suggest to the Minister that the present scale of payments be reviewed at the earliest possible date. It was defeated by 3 votes to 2, with 12 of our faithful administrators abstaining.

Mr. J. C. Gilbert Retires

Mr. J. C. Gilbert, Clerk of the London Executive Council, has retired on reaching the age limit of 65 years, and his many friends will wish that he may long be spared to enjoy his retirement. He was appointed to the staff of the London Insurance Committee in 1913, having previously served in the Education Department of Kent County Council. In 1926 he was made Deputy Clerk of the Insurance Committee, and six years later he became Clerk. This long experience, combined with a remarkable memory for precedents, was of great value to his colleagues, and his charm of manner and the clarity with which he expressed himself evoked their admiration. He has been honoured twice—he holds the Coronation Medal and is an Officer of the Order of the British Empire.

Questions Answered

Government's 8% Contribution

Q.—*In the Supplement of Dec. 25, 1948 (p. 235), you state that "the Government's contribution is part of the practitioner's income for the purposes of the Spens calculation [of salary]. A doctor over 65 pays no superannuation. Does the Government credit him with 8%? Is this payable to the practitioner in any form—say on retirement?"*

A.—A doctor who is over 65 years of age on entering the N.H.S. cannot participate in the superannuation scheme and is not liable to have contributions deducted from his remuneration. He will not therefore receive the benefit of the Government's contribution of 8%. The normal retiring age is 65, but a practitioner on an executive council list may apply at any time between the ages of 60 and 65 for an extension of pensionable age up to but not beyond the age of 70. The question of the return of the Government's contribution of 8% in these circumstances is now being examined by the Superannuation Committee.

Eligibility for Compensation

Q.—*Is there any difference between not joining the new Health Service before July 5 and resigning after qualifying for compensation on July 5? Why is the medical profession not now in a much stronger bargaining position than before qualifying for compensation in July?*

A.—A practitioner whose name was included on the list of a local executive council on or before July 5 becomes eligible for compensation in respect of the loss of the right to sell the goodwill of his practice. The regulations enable a practitioner to claim immediate payment of compensation on retirement from the public Service. Thus any practitioner on retirement is now certain of his compensation, and to that extent the medical profession is in a stronger bargaining position than it was before July 5.

Injections Ordered by Specialist

Q.—*A registered patient goes privately to a consultant for asthma, and is given material which has to be injected weekly for at least 30 weeks. Is any charge to be made for the injecting, or is this provided free under the N.H.S.?*

A.—The patient's general medical practitioner would be expected to give the injections as part of his terms of service under the Act and is debarred from charging any fee to the patient concerned.

Locums

Q.—*What is the position of locumtenents in the new N.H.S.?*

A.—Any medical practitioner may engage the services of a locumtenent under the National Health Service. The locumtenent enters into private arrangements with the principal employing him, and details of remuneration and contract, etc., are settled direct between the two. Vacancies for locums are still advertised in the medical press, and the Medical Practices Advisory Bureau maintains lists of locums available and practitioners requiring locums.

Correspondence

Graduated Capitation Fee

SIR.—I was extremely interested to read the Secretary's remarks regarding a graduated capitation fee in the *Supplement* of Jan. 15 (p. 21), and I would suggest that a plan such as this is an important part of any demand for increased capitation fee.

If it is true, as I think it is, that an essential part of the hardships now being experienced are falling on those with small or medium-sized lists, and if, as I suspect, Spens is being implemented (apart from an adequate betterment factor) for those with lists standing at or about 4,000, are we really in a position to demand a flat increase in the capitation fee? If we ask for 30s. this gives 4,000-list men £6,000 a year. Is this a reasonable demand? I suggest there are two important considerations:

(a) That remuneration should correspond as far as possible with work done; and here it is not only quantity but quality that must be rewarded.

(b) The tradition of the family doctor should be encouraged, and the standard of medicine in general practice should be kept as high as possible.

There are four main functions at present carried out by G.P.s.

(1) Certification of fitness or unfitness for work, and acting as a signpost to out-patient departments.

(2) Proper examination and diagnosis of the sick, helped when necessary by the consultant services, while still maintaining responsibility for the patient as a whole.

(3) Treatment of such cases as can be dealt with at home or surgery. This may necessitate daily visits, regular injections, minor surgical procedures (circumcisions, plasters, etc.), and anaesthetics.

(4) Acting as family friend and health adviser (feeding difficulties to geriatrics).

Now, the larger a man's list is the more he must tend to perform function (1) to the exclusion of the others, whereas I maintain that the type of doctor we should aim at producing, and should encourage in his work, is the one who performs the three latter functions. In this connexion the letter of Dr. Reginald Deane (*Supplement*, Jan. 1, p. 5) will repay close study. His figure for an optimum list for a fully occupied doctor is 1,500, and I agree that this is a reasonable estimate. I am well aware that many men deal with far more than this number and do it efficiently, but "dealing" with a patient and doctoring are two very different things. I am confident that in any but the most congested areas a list of 2,500 is far more than a man can doctor properly. The figure might be reached with reorganized surgery premises and really efficient and adequate help, but should not be exceeded.

If, then, we grant that a man with 2,500 on his list who is doing his job well is doing a very full day's work, we must agree that he should have at least a comparable income to the man with 4,000 patients with out-patient departments and clinics of every description on his doorstep.

It is vitally important, also, that the "new entry" should be encouraged to go in for good doctoring—to the great advantage of the patients, the hospitals, which will have less work, and the honour and standing of the medical profession in this country. It is beyond dispute that in diagnosis a careful history is of the greatest importance. This cannot be obtained in a few minutes in an overcrowded surgery, and so, if work is to be done well, time is essential, and this means fewer patients: no amount of "efficiency" on the part of the G.P. can make up for this.

As a practical measure I consider that the graduated capitation fee, so arranged that lists between 1,000 and 2,500 are encouraged, is the best answer in the present circumstances. Other points I would urge include:

(i) Adequate mileage payments.

(ii) Payment for special services—i.e., minor operations, anaesthetics, etc.

(iii) The right to order expendable items of equipment (needles, syringes, dressings, etc.) and drugs required for emergencies or personal administration on form E.C.10.

Present allowances of 2s. 6d. per 100 patients are ridiculously inadequate and again penalize the man with a small list, who

does more treatment and therefore uses more apparatus than the man with a full list.—I am, etc.,

Liverpool.

C. W. WARNER.

A Fighting Association

SIR,—Mr. Winston Churchill once warned us (I am unable to quote exactly from memory) against building a society where initiative, thrift, and industry went unrewarded and only officials met with respect. I am no ardent Tory, yet I feel that this pronouncement is very pertinent to present-day life.

The N.H.S. has changed the face of medicine. Many doctors are finding their initiative, thrift, and industry unrewarded, and they are exhausted butting their heads against the brick wall of officialdom. Week after week one reads letters in the *B.M.J.*, angry letters uncovering injustices and anomalies, until one is brought to a frame of mind wherein the N.H.S. assumes the proportions of a national calamity. This is undoubtedly an aberration. There is of course much that is good in the N.H.S. I dare say that the next generation of doctors will work amicably and successfully under the Ministry. In fact, while bearing in mind that adjustment to a new situation must take time, there is no real reason why *this* generation should not find an amicable working arrangement.

An arrangement will not be brought into being, however, by *B.M.J.* letter-writing. It is all very well for us to sublimate our irate energy with pen and paper, but no advance is achieved. Protests and plans appear with monotonous regularity; indignation and dismay fill the correspondence columns; colleagues face hardship and distress; but the B.M.A. with its cargo of Negotiating Committees sails on like a stately Spanish galleon, aloof amid the grapeshot and the fire.

The seemingly complacent attitude of the B.M.A. and the slow-moving (if constitutional) machinery of its negotiations are annoying doctors intensely. I do the Negotiating Committees an injustice; they are undoubtedly energetic and well-intentioned. But why, when we ask for action and leadership, are we fobbed off with editorials? The Secretary's Report in the *Supplement* of Jan. 15 (p. 21) (just received) shows that something effectual has been done in obtaining a larger Mileage Fund. But I still feel we are using a toy spade in place of the necessary steam-shovel.

There is a great indignation in the profession which could surely be canalized to convert our conditions of work and remuneration into something befitting a noble profession. The G.P. as he surveys his surgery queue still groans. The specialist bitterly compares his salary with that of the dentist and optician. And the advertisement columns still offer £200 or £150 "with full residential emoluments" to us of the younger set who are deemed unworthy of a labourer's wage.

There is a call for something big and forceful to be done, and quickly. One agrees whole-heartedly with letters like those of Drs. H. M. Stanley Turner (*Supplement*, Jan. 15, p. 25) and R. E. M. Coke Harvey (p. 28) which plead for effective action. Before all initiative drains away, why not adopt the plan to cease all certification if just demands are not met by a certain date? Or even Dr. R. W. Cockshut's course (Jan. 8, p. 16) of threatened mass resignation?

The profession needs unity above all else. Let us strive for fair conditions for all doctors, no matter in what type of employment. And may I offer a plea that younger doctors, returning to hospital jobs after serving in H.M. Forces and perhaps with family commitments, be not forgotten? They are facing lean years. A weak B.M.A. will leave the profession joyless and servile. With a fighting Association of unified doctors this can be, even yet, a great period in the history of British medicine.—I am, etc.,

Warrington

J. K. W. MORRICE.

Lack of Support for Negotiators

SIR—I feel that Dr J. J. Kennedy's comments (*Supplement*, Jan. 22, p. 38) on my letter in the *Supplement* of Jan. 8 (p. 16) require an answer. It is obvious that Dr. Kennedy missed the whole point of my letter, which was to publicize the fact that it was the rural practitioners who pressed for an early Branch meeting, not myself. I did not organize the meeting on a Saturday afternoon through choice, but because that was the only day that Dr. Grey Turner could manage.

Moreover, I wonder whether Dr. Kennedy realizes to what conclusion his letter must logically lead if the facts he reports in it are true? Should the B.M.A. cease to concern itself at all with the pleas of any section of doctors because the latter are far too busy to help themselves?

I would like to assure Dr. Kennedy that I am very much aware of the present troubles and difficulties of all sections of the medical profession. No Branch secretary is allowed to remain in ignorance of these facts very long. At the same time I am convinced that if the medical profession, and particularly the rural practitioners, have a case then they must fight hard. Few officials can do anything without solid support.—I am, etc.,

G. M. WODDIS,

Hon. Secretary,
Nottingham Branch, B.M.A.

Ultimatum

SIR,—I have noted with ever-increasing interest the large volume of dissatisfaction now prevailing in our profession against the N.H.S. or some part thereof. The hardships of our rural brethren are patent for all to see, and even those such as I who have not lost financially by the Act are nevertheless chafing under the yoke of this dictatorial oligarchy who now govern us.

The point I should like to stress is just this—that the time cannot be long delayed now when the Ministry will be forced by circumstances to call in the help of the medical, dental, and nursing services to find a means of escape from the financial impasse which is hanging over the Government like the sword of Damocles. The time is surely ripe now to tabulate in advance all our grievances in readiness for the day when Bevan must and will approach us hat in hand and presumably also with a disarming smile. On that day we must, through our accredited representatives, present our case as an ultimatum, thereby employing the only language which he appears to comprehend.

I feel bound also to mention one point which has been raised by the better-class laity in this area—namely, the outrage of compulsory payment of contributions to this health and pensions scheme against their free will, and particularly where they have no intention of availing themselves of the very doubtful benefits conferred by it. This anomaly is most apparent where we in the medical profession are concerned, and I personally consider that the compulsory stamping of a card by a professional person is little short of an insult and must be stopped at the earliest possible moment.—I am, etc.,

Kirkcaldy, Fife.

C. I. IRVINE-JONES.

Better Conditions or Resign

SIR,—We have worked the N.H.S. now for over six months, and have seen it fail to attain its objects to an even greater extent than most of us feared. It was to increase the efficiency of medical treatment over the country. We can see even in ourselves the standard of our work rapidly deteriorating, we have to give so much time to the non-essentials. It was to make it easier for a young doctor to start in practice. Now unless he happens to be one of a fortunate few it is impossible for him to start unless his available capital is sufficient to enable him to pay his way for some years until his N.H.S. income is large enough to meet his yearly expenses. It was to encourage group practice. Now we see partnerships being terminated all over the country because regulations make it economically advantageous to do so. It was to give doctors financial and professional security and freedom. Now few of us can hope to end the year without increased overdrafts, and we see our freedom more and more curbed by slow degrees.

It is time our leaders realized the urgency of our position, or, if they will not, that we elect new ones. They will be elected not to negotiate with the Minister but to go to him with at least 10,000 (one might even hope with 15,000) resignations in one hand, and in the other our reasoned and equitable conditions for a satisfactory service, professionally and economically secure for the profession and satisfactory for the public. In their approach to the Minister they will adopt his form of negotiation—*Ipse dixit*. With the profession united behind them the Minister would be powerless.—I am, etc.,

Ewell, Surrey.

J. V. COPE.

Spens and Superannuation

SIR.—Statements made in the *Supplement* of Dec. 25, 1948 (p. 235), under "The Secretary Reports" call for question and comment. In the early negotiation days we were told that the superannuation scheme was generous. If the Secretary's statement is now accurate then of course there is no generosity. On the contrary, it means that there is a compulsory deduction from actual earnings under "Spens" to provide both sources of contribution. Put in another way, it means that 6% net is deducted from the doctor's cheque and in addition the 8% net is actually being withheld by the Treasury from the real Spens award. If the Secretary's interpretation is accurate, which I doubt, then there should be amendment of procedure in certain circumstances to ensure uniformity of implementation of Spens.

(1) Doctors over 65 who do not contribute should receive back the 8% which is apparently being withheld.

(2) In the case of death, retirement, or dismissal within 10 years (in some cases 5 years only) there is a return of the practitioner's contributions with compound interest and minus tax, but no refund of the Government's 8% withholdings.

(3) The option. The existence of an anomaly is shown by the fact that those practitioners exercising the option under superannuation do not pay their 6% and actually receive the 8%, and of course pay income tax on both.

Obviously there are inconsistencies and anomalies. If the Secretary is correct there is at any rate no generosity on the part of the Government in establishing the superannuation scheme. Instead it compulsorily deducts and withholds parts of our earnings, acts as banker, and uses our money to provide the benefits under the scheme which we are compelled to join if we take service within the Act.—I am, etc.,

Walsall, Staffs.

A. B. DAVIES.

* * The statement in Para. (2) above overlooks certain circumstances in which the contributor with less than 10 years' service may receive benefits equivalent to or greater than the amount of his own contributions and the Government's contributions. For example:

(a) In the event of retirement after five years' service owing to permanent ill-health a short-service gratuity will be payable equal to the average remuneration.

(b) An injury pension may be granted at the discretion of the Minister in the event of permanent incapacity through accident or injury in the discharge of duty and which is specifically attributable to the nature of the duties. There is no qualifying period for this benefit, which takes the form of an annual allowance not exceeding two-thirds of the average remuneration.

(c) A death gratuity is payable provided five years' service has been completed. The gratuity in the case of a general practitioner is a sum equal to the greatest of

- (i) 4½% of the net remuneration for the total average of service, or
- (ii) the practitioner's contributions with interest, or
- (iii) the average remuneration during the last three years' service.

It is true that in cases where no benefit or transfer value is payable the practitioner's contributions are refunded with compound interest of 2½%, while the Minister's contributions are not refunded.—Ed., *B.M.J.*

Salaries of Opticians and G.P.s

SIR.—Mr. G. H. Giles is to be congratulated on the ingenuity of his last letter (*Supplement*, Jan. 8, p. 19), but I fear he is defending an untenable position. No one has decried the optician as he suggests, but everyone has a right, and even a duty, to protest against a waste of public money. The general practitioner has even more cause, for the Minister is reported to have given as one reason for not increasing the capitation fee the fact that the National Health Service is already costing too much.

On Jan. 8 Mr. Giles stated that the optician works a 10-12-hour day because on top of six hours' work on refractions he still has other tasks to perform. But on Nov. 27, 1948 (p. 196), he said that in a 6-hour day he could see only six patients because of these other tasks. Really he cannot have it both ways. If he refracts for six hours (present claim) he can see at least 12 patients and receive for refractions only at least £2,250 per annum. If he does all his work in six hours (claim of

Nov. 27) he is very much under-employed, but nevertheless receives £1,125 per annum for refractions only.

Mr. Giles claims that his working expenses are considerably higher than those of the G.P. Does he really believe this? In his list he gives a qualified assistant's salary, but as the effect of this would be to double the work done and pay received, we will not consider it further. He considers as absolutely essential his secretary-receptionist to answer the phone, etc. But who does he imagine answers a midwife's phone? Not her secretary surely? The mechanic and the workshop expenses he mentions will be for dispensing and repair work—matters which I have completely left out of the figures given for remuneration and which Mr. Stenhouse Stewart (Dec. 18, p. 231) left out of his figure of £150. His rent and rates need be no higher than the doctor's; after all, a shop-front in the centre of the town is hardly a necessity for a professional man. His expenses on lighting will probably be about the same. Those on the telephone will certainly be less, for he will never know those hour-long sessions at the phone trying to secure a hospital bed. There is one expense, and one only, which does not have its counterpart for the G.P.—namely, advertising—and it is, hard to see why this should be paid for out of public funds.

Mr. Giles gives among the time-consuming trivialities of his life the making out of reports to doctors. Since the inception of the National Health Service I must have issued hundreds of forms O.S.C.I. but in only one case have I received a report from an optician.

We must all applaud Mr. Giles's remarks on the desirability of having enough time to give one's patients an adequate examination. It is a strange comment on the muddle-headedness of the present Government that all work in the National Health Service has to be hurried with the sole exception of that done by the optician. But perhaps we are wrong—perhaps the refracting power of the cornea and lens is the most important attribute of the body, and physicians, surgeons, and ophthalmologists only exist so as to provide an adequate background for the refractionist's all-important work.—I am, etc.,

Silver End, Essex

J. W. NICHOLAS.

Questions for a Plebiscite

SIR.—We are asked to support the B.M.A. and its Negotiating Committee in their efforts to obtain reasonable remuneration for us from the Ministry. But what is the figure of the capitation fee they are asking for? Has the amount been accepted by the profession as a whole? Surely they should have a definite mandate from all practitioners employed under the N.H.S. which states the fee acceptable by them. From letters appearing regularly in the *B.M.J.* the capitation fee considered just seems to be from 30s. to 40s. per head. Is this the fee being negotiated for?

The Spens Report seems to be used in argument by both sides and no one appears to be quite sure what the fee at the present day should be according to that report. So why not end the argument by taking another plebiscite, the first question on it being: "What is the minimum capitation fee you will accept?"

Practitioners have had six months' experience in working the N.H.S. and have received two cheques, so they can now give a reply from practical experience; but before answering this question the practitioner should consider very carefully, as the future of the profession of medicine depends largely on what terms we get now. Our salary must be adequate and sufficient to enable us to educate our children as well as we have been and for us to enjoy some of the amenities of life. How else can we ensure that the future entrants to the profession will equal the type of previous generations?

I maintain that payment by capitation fee is not the ideal method of payment—too much temptation to degeneration into Dyak or Red Indian witch doctors—but as it has been accepted we must make the best of a bad system. Coupled with the capitation fee is the question of maximum number on list. This is Question 2 in the plebiscite.

And now we come to superannuation. The general practitioners are key men in the National Health Service, which is a main cog in the social security scheme, and yet they are left to face retirement on a pension which is absolutely inadequate. A doctor now aged about 55 years can put in 10 years of service under the new scheme and so

qualify for a pension when 65. If he has a panel of 1,500, which is as many as the majority of country doctors will have, and for that matter as many as town men too, he will get a pension of £126 per annum, and when he dies his widow will get £42 per annum. If he applies to the local executive council for permission to work until he is 70 years old, and if this is granted, his pension will be £189 per annum and that for his widow £63 per annum.

His income during these working years will be about £1,200 per annum, of which at least half will be swallowed up by practice expenses, leaving him no chance to save for his old age but very great possibility of having to dip into savings in order to carry on. He gets no credit for his years of service under the old National Health Insurance in the computation of a pension. Surely those past years of service in a national scheme under which he was grossly underpaid should be taken into consideration, as I suggested in the scheme I published in the *Supplement* of March 15, 1941, p. 29.

This is our third question: "Do you insist that the years of service under the N.H.I. be credited when computing superannuation?" Judging from the Minister's replies in the House to Sir Ernest Graham-Little (*Journal*, Dec. 11, 1948, p. 1042; Dec. 25, 1948, p. 1126) we cannot count on achieving very much unless the B.M.A. has a definite mandate from a united profession and is empowered to take drastic action if the Minister does not accede to their just requests without evasion, equivocation, or mental reservation of any kind. The B.M.A. must have our united support in the form of a mass resignation to be used if full demands are not met.

Hence Question 4: "Will you agree to sign a form of resignation to be used by the B.M.A. if negotiations break down, subject to the proviso that if less than 66% to 75% resignations were not received by the B.M.A. they would not be used?"

But surely at least 75% of the medical profession has the guts to put up a determined fight for the last chance to prevent a learned and honourable profession from sliding down the scale to become a third-rate occupation. A trade union would put up a fight for its workers, so surely the B.M.A. will not fail through lack of courage and force.

Let me again set out the questions on the plebiscite: (1) What is the minimum capitation fee you will accept? (2) What do you consider maximum number of persons for one practitioner's list? (3) Do you insist that your years of service under the N.H.I. be credited in computing superannuation? (4) Do you agree to sign a form of resignation to be used by the B.M.A. if these demands are not met absolutely, provided the B.M.A. receives a mass resignation from 60% to 75% of practitioners?

These matters are serious and urgent. We drifted along for years with an inadequate capitation fee under the N.H.I., but then we could subsidize that from our private practice. Now we must sink or swim on what we receive from the N.H.S.—I am, etc.,

Wetherby, Yorks

S. T. PYBUS

Another Plebiscite

SIR—From the correspondence columns of the *Supplement* it would appear that an ever-increasing percentage of doctors, both general practitioners and consultants, are wholly dissatisfied with conditions of service under the National Health Service. May I suggest that the present plight is largely due to the nasty and ill-timed second plebiscite, which was thrust at the eleventh hour upon a confused profession by the British Medical Association?

Now that we have all had time adequately to reflect upon our folly, and to assess what service under the present Act really means, is it not now opportune to present a third plebiscite upon the following general lines.

(1) Are you satisfied with conditions of service under the National Health Act?

(2) If not, would you be prepared to withdraw from the Service on a given date, provided a majority vote is obtained?

I personally feel little doubt about the doctors' answer, which would arm us for future negotiations with a bigger stick than the one our present masters are so fond of waving at all sundry.—I am, etc.,

J. C. W. L.

A. C. BOYLE

Dictatorial Action

SIR—The experience of Dr. E. S. A. Ashe with the Cheshire Executive Council (*Supplement*, Jan. 15, p. 27) is mild compared with my experience of the London Executive Council. On Dec. 28 last the London Executive Council wrote to me saying that I had acted irregularly in accepting cards for a colleague who practises at my premises. I was not invited to

the meeting nor informed that I was to be discussed, and hence had no opportunity of hearing and of refuting such accusations. I was invited to express an opinion on their conclusion that "I had acted in a somewhat irregular manner."

This letter was treated with the contempt which it merited. To-day (Jan. 14) I received a second letter asking me to reply without further delay. If this is not dictatorial I should like to know what is. It took the same council more than three months to reply to my letter asking for the basic salary.

I resigned from the scheme on Dec. 31, 1948, and such a demand to one who is not in the scheme augurs badly for the treatment of those doctors who are trying to work the scheme. I'm glad I resigned.—I am, etc.,

London, S.W.6

N. J. CALDWELL

Refusal of Basic Salary

SIR,—Dr. E. S. A. Ashe's letter (*Supplement*, Jan. 15, p. 27) is quite misleading. Every practitioner in Cheshire who claimed a basic salary received a questionnaire from the Local Medical Committee. Wherever the questionnaire was not returned the Local Medical Committee was unable to recommend to the Executive Council that the claim to the basic salary had been established.—I am, etc.,

J. B. BENNETT,
Hon. Secretary,
Chester Local Medical Committee

Appealing for Basic Salary

SIR,—Dr. E. Granger's experience (*Supplement*, Jan. 15, p. 241) with his Local Medical Committee is typical. I received a refusal in precisely the same words. As my pittance is less than my mortgages, I have been scraping by through advances on the current quarters while waiting like a miserably threadbare Micawber for "something to turn up." This advance has suddenly been refused me in the same dictatorial manner. A further application under the regulations has received still less attention, the committee refusing even to consider it. Not only are we to be financially ruined by statute but shamed and insulted by county medical soviets.

Where do we go from here? Surely the answer is obvious. Immediate action or Carey Street is our only alternative now. The time for interminable sterile negotiation is past. The British Medical Association is our association, pledged in its foundation to carry out the will of its members. The unanimous will of its members to-day is for a strong lead. Upon my soul I cannot see much signs of it. Give us that lead, at once, now to-day! And we, the profession, will follow that lead through hell and high water. Put out to every member now this question: "Are you prepared to resign unless immediate satisfaction is obtained from the Ministry?"—and see what the result will be. You will then have a potent weapon for, at the very least, independent arbitration.

We are governed by a band of ex-professional strikers. There is no other procedure which they understand. I have taken it on myself personally to warn the Minister and have begged him to see the red light. He will not do so until that red light is blazingly active. I ask our Association to answer. What are you waiting for?—I am, etc.,

Loughton, Essex.

G. B. KIRKLAND

New Method of Remuneration

SIR,—I offer the following suggestions for working out an equitable basis of remuneration for general practitioners:

(1) A committee be set up to determine the maximum number of patients a doctor of the age group 40–54 can attend to adequately in any particular area. The country should be divided into classified areas, as the maximum number of patients that can be attended to will be dependent on the density of population. The age group 40–54 has been chosen as this includes the group of doctors in their prime of health and also mature in experience of practice. This group also has the highest percentage of maximum income in accordance with the Spens Report.

(2) The remuneration should be so assessed that in any of these areas maximum lists should receive equally the higher rates of income recommended by the Spens Committee. It is doubtful whether the Mileage Fund can be used effectively for

this purpose. What I propose is that if in an area the committee finds that the maximum list should be 1,500, compared with a maximum list of another area of 3,000, then the capitation fee in that area should be double that of the latter area. The Mileage Fund can then be used for its proper purpose of reimbursing practitioners for the actual expense incurred attending to distant patients.

(3) An increased capitation fee for the first 20% of the maximum list in any area, and then an equal capitation fee for the remaining 80% of the list.

(4) If it is not possible to limit lists in any area to the maximum list as advised by the committee, then doctors in that area be permitted to accept patients above the maximum list, but at a reduced capitation fee.—I am, etc.,

London, S.W.18.

D. BILLIG.

Equitable Compensation

SIR,—Now that an amendment to the N.H.S. Act is to be introduced in Parliament an opportunity will be provided to have the regulations regarding the apportionment of compensation altered so as to give a more equitable distribution. Under present regulations a doctor whose practice is worth one year's purchase receives the same as a doctor whose practice is worth two or more years' purchase. Could a small committee be appointed by the B.M.A. now, when another opportunity will be available to look into the matter, which, if not put right, will have disastrous results for those who are relying on their capital for retirement?—I am, etc.,

Liverpool.

JAMES WELLWOOD.

Chiropodist's Services

SIR,—I should like to heartily endorse all those letters in your columns relating to the gross inadequacy of the present remuneration of general practitioners, and I agree that drastic action is imperative now. In this town the average attendance per patient per year is at least ten, and this divided into the capitation fee works out at under 2s. per visit.

A chiropodist called on me the other day and told me that her charges were 3s. one foot, 5s. two feet, and 7s. 6d. a visit. We have reached a low state indeed when a chiropodist's services are worth three times as much as those of a doctor.—I am, etc.,

Harrogate.

J. C. WARD.

Fees for Anaesthetics

SIR,—I have seen no mention made of the cut-price salary which the G.P. is being offered for performing specialist duties at a hospital, and I should be glad to know if the Negotiating Committee intends to take any action in the matter. Interim contracts are being offered with a salary of £100 per annum for one session per week instead of the full £200, and it is my contention that if a G.P. performs specialist duties he should be paid at specialist rates. For example, an anaesthetist may give four anaesthetics at a session, which means that he is paid the princely sum of 10s. 6d. per case, and such cases may include a cholecystectomy, an appendicectomy, etc. Yet for a short gas anaesthetic for a dentist to extract one tooth he is paid 10s., and for one general anaesthetic to a fellow practitioner to apply forceps he receives £1 15s.

Even the full salary of four guineas per session seems cut price enough, and one can only hope that every G.P. who is offered a half-price interim contract of two guineas per session will refuse it, and that there will be no Quislings among us short-sighted enough to accept such outrageous cut prices, since it is only by loyalty to each other that we can ever expect to gain better terms of service for all.—I am, etc.,

Egglefield Green, Surrey.

W. E. R. BRANCH.

Shop-walkers

SIR,—The figures for my income are: Average income for the two years before the Service started (accountant's figures)—£728 per year. Number on list, October, 1948—1,141. Amount of cheque: £181 17s. 5d., plus £71 14s. 9d. (basic salary), less £9 17s. 9d. (superannuation)—total, £243 14s. 5d.

I started a new banking account on July 5 which did not contain half the living costs of the family and self but included out of the expenses of practice, and after paying above cheque I was still overdrawn about £12 plus. At the moment I am

nearly £400 overdrawn. Would Aneurin Bevan be a G.P. working under such conditions and for such long hours? We are doing our best to give our best and to make this scheme work, and if it fails—as surely it will if these conditions are not altered drastically and quickly—then Bevan's will be the ignominious glory for its failure, and if this happens it will cost the next election. I am not politically minded, but I do know that 1 plus 1 makes 2, and when we are led to believe that $\frac{1}{2}$ plus $\frac{1}{2}$ equals 1, and that 2s. 6d. per 100 patients covers the cost of dressings, etc., per year, then it is high time that the Negotiating Committee had someone who can think logically and clearly to negotiate with, and they should take steps to secure this.

The greater tragedy of it all is that within one generation or less the family doctor will be no more. Instead there will be a "shop-walker" directing the patients to different departments. The patient's illness will be his own responsibility; to see that he gets the treatment and carries it out will be his own responsibility; it will be up to him to report progress, etc. Responsibilities for which doctors now assume the burden will soon be thrust on the patients themselves—to their detriment.

We as doctors did not work for the money in it before July 5, but we knew that we could make both ends meet and that we could look forward to giving our kiddies a decent education, and maintain a decent standard of living. Indeed, to most practitioners the £ s. d. side has always been the most loathsome side of our work. We have always worked hard without thought to overtime and hours of work, and without any thought as to whether any one patient would pay us a bean or not, and we have struggled along without complaint.

So far we carry on just the same, giving the best we can under the increased burden of more work, which does not worry us so much, but the other burdens on our shoulders—and they are very heavy ones—the burden of financial insecurity, the burden of loss of freedom in many branches of doctoring, the burden of impending directorship and dictatorship from above, the burden of being told what we can prescribe and what we cannot, the burden of being told which consultant we must have, etc., etc., are just about killing, and contrary to any conception of freedom which we previously had.

Fortunately it is such a sad state of affairs that I do not think that it can or will last very long, as it is all so contrary to the British way of life and also to human nature. No government can alter the latter, nor will they be able to destroy the best that is in us. But the tragedy is that they may in time be able to breed and educate, or perhaps only educate, a generation that see only their point of view. Hitler nearly did, but presumably he is dead now. Let this country not repeat his mistake. The value of this service to the community is too great for us to allow any one political party to ruin it. Let us see to it that it becomes the best possible service, staffed by "willing horses" eager to pull their weight and able to breathe fresh air.—I am, etc.,

Cae'narvonshire.

G.P.

Representation of Tuberculosis Workers

SIR,—The letter from Dr. William D. Gray (*Supplement*, Jan. 1, p. 8) criticizes the Joint Tuberculosis Council for (a) postponing any decision with regard to regional representation on its Council for a period of six months, (b) refusing representation to the newly founded Liverpool Regional Tuberculosis Society, and (c) having an unrepresentative constitution.

A copy of the Council's Constitution is enclosed, and it will be noted that all existing clinical tuberculosis associations and societies are represented, the only exceptions being those associations having limited constitutions—e.g., areas of membership limited by local authority boundaries. The Council's interests are wide and are not limited to terms and conditions of service; in fact the latter in the past have comprised only a small fraction of the Council's work. It is not necessary to detail the subjects considered by the Council, as these are faithfully reported in your *Journal* from time to time. It will be noticed in the Constitution that Rule 5 restricts the size of the Council. A large deliberating body would be unwieldy and would make it impossible to conduct business in the limited time available for meetings.

To avoid delay, Liverpool members of the North-west Tuberculosis Society should put their views forward to that

body, whose representatives could then bring them before the Joint Tuberculosis Council. This is the constitutional and most rapid and effective way of proceeding.

It was foreseen that regional groupings would probably result in the formation of new clinical societies and that these societies would seek membership of the Council. There is ample time for the new societies to show their worth before any question of displacement of the old and tried clinical associations in favour of the new bodies is considered.

It is appreciated that the Joint Tuberculosis Council is not primarily constituted to consider terms and conditions of service. The only reason that the Council is taking an active part in work of this nature at the present time is the absence of representation of tuberculosis workers on the Central Consultant and Specialists Committee and the lack of an alternative avenue of approach other than through the Tuberculosis Group of the Society of Medical Officers of Health. This latter body is better constituted to deal with such matters as terms of service, but joint action is taking place at the moment to ensure full support for the representations to be made.—We are, etc.,

D. P. SUTHERLAND,
Chairman, Joint Tuberculosis Council.

N. J. ENGLAND,
Hon. Sec., Joint Tuberculosis Council.

New Tourist Attraction

SIR,—May I suggest that in order to encourage foreign visitors to come to Britain, bringing with them much-needed dollars, the B.M.A. should circularize travel agencies, British, American, and Continental, to point out one of the almost incredible advantages of a visit to this country? Foreigners can have, at the expense of the British taxpayer and at no charge to themselves, new false teeth, blood counts, radiological examinations; they can have their prostates removed, their children delivered, and free spectacles; and, not being private patients, free medicine as well. Foreigners will hardly believe this, but owing to the wonderful service the British doctors now give, it is perfectly true.

It is, unfortunately, also true that if an Englishman living here requires a non-urgent operation, such as removal of a cartilage from his knee, he has to wait about sixteen months before he can have it done. But foreigners should come here none the less, get their out-patient appointments now, and come back next year and have their operations and spectacles and their false teeth. It seems rather unfair that if they have indigestion they will have to pay for their extra milk and eggs. This latter point had better be left out of the advertisement.—I am, etc.,

Cambridge

E. V. BEVAN.

Abolish Evening Surgeries

SIR,—Abolition of evening surgeries is one of the demands that should be made by the medical profession. The doctor is looked on as being tireless and expected to be at everyone's beck and call day and night. The position is worsened to-day by the increased clerical work due to forms, prescriptions, certificates, etc. A morning and afternoon surgery fairly close to each other would enable doctors to do out-patient work before and after their surgery hours, and give them their evenings to get ahead with clerical work, study, home life, etc. Why should men whose education is so costly and who have had to devote such a lot of time to their medical curriculum be treated like this?—long and tiring hours doing skilled and responsible work, increased work, rising costs all the time, and a reduced income.

If a patient is ill enough to need to see a doctor, he should surely be given time off to see the doctor during his morning or afternoon surgery. Besides this, it will be more beneficial to the patient, as his evening will then be free.—I am, etc.,

Dr. J. A. Sykes

J. A. H. SYKES.

SIR,—I trust you will insert a few lines from me agreeing in every way with Dr. Victor M. Seifert (*Supplement*, Jan. 15, p. 24) of London, re evening surgeries. What a wicked waste

of time for doctor, chemist, and patient! Dr. Seifert is a luckier man than I am because in this district there is no local cinema and the only recreation left to a person in this area is a visit to the surgery in the evening.

However, he will be pleased to learn that I have given up this useless form of amusement and spend the time in visiting the really sick people. I have a morning surgery every day, and it is a solid mass of human beings "shoulder to shoulder." If I had an evening surgery I'm afraid that midnight would not see me in bed.

A few days ago an old man of 82 informed me that he used to enjoy the evening surgery and a chat with friends, but now he has to get up early and go to the morning surgery for his "bottle." Shops, banks, and other professions close down at a normal hour, and why should doctors be so foolish as to invite a lot of people to a room at night and encourage them to go sick? It is about time we had sense.—I am, etc.,

Biggin Hill, Kent.

J. J. ROHAN

Abolish Assistantships

SIR,—A few months ago I was released from the R.A.M.C. after serving 5½ years mainly in hospitals at home and abroad. Now I am an assistant to a G.P. with a large practice with a view to partnership.

During my short service in G.P. I have come to the conclusion that an experienced assistant can carry a very heavy load. Here in the course of six months I have carried on the practice for at least 11 weeks single-handed, and during the remainder of the time I have had scarcely any leisure at all in which to read or lead a normal home life. I have no doubt that there are other assistants in a similar plight. Not only this, but there are at least four other doctors treating patients in the district. The other day I found that another doctor from about four miles away was treating the children whilst I was called in to treat one of the parents.

Our practice extends into and beyond a village eight miles away in which there are two doctors. Surely something is wrong with a system like this. In addition to this on several occasions patients of other visiting doctors have come to me either in emergency or, as I had the other day, because it was too bad a day to go to ———, a village four miles away. The whole thing seems to be ridiculous.

May I make the following suggestion for consideration? The old G.P.'s enormous practice should be ended; G.P.'s lists should be reduced to under 3,000; abolish forthwith assistantship and partnership; let doctors, young or older, practise as doctors and not as assistants or partners; procure all information possible about under-doctored areas—many assistants could furnish this; all doctors should be paid by local executive councils and not by individuals; minimum adequate salaries should be paid to single and married men according to years of qualification.

I feel that many assistants are being exploited under this trainee scheme, which should be abolished. Special courses for young G.P.'s could be arranged as courses were arranged in the Services. After all, a newly qualified doctor is a doctor, and would do very good service when posted to any area.

If the country were properly divided into areas the public would have better service. G.P.'s will hang on to enormous practices until the bitter end, working themselves, their assistants, and their partners to death, all for the sake of £ s. d. So let's have fairness all round. Put all doctors, young and old, on a level footing: the young will learn by experience and special courses of instruction, and there are plenty of good consultants available when necessary.

The N.H.S. could be a success if all doctors were treated as doctors and paid as such, and not as assistants or partners.—I am, etc.,

ASSISTANT.

Organization of Council

SIR,—I have read with great interest your report of the Proceedings of Council (*Supplement*, Jan. 22, p. 33) and am prompted to reply to Dr. Carter's consideration that the Winchester memorandum was ill-informed when it stated that the Council was out of touch with the rank and file of the profession.

The Winchester Division, as you know, is now in possession of a great deal of information from Divisions all over the British Isles on the organization of the B.M.A. in general and of Council in particular. I can assure you that very few of these contain any comments suggesting that Winchester was ill-informed, on the contrary, we have been surprised at the vehemence with which a number of Divisions have approved of our remarks and, as our revised memorandum shows, have been prepared to go even further in reform than we originally proposed.

If, as we believe, Dr Carter, as chairman of the Bourne-mouth Division, has so far not allowed his Division to discuss our memorandum, we have reason to doubt whether he is well-informed even of the opinions of his own members on the question of organization, and we certainly cannot believe that he has the authority under such conditions to criticize the opinion of a Division so strongly backed by others.

Dr Pridham's remarks in putting his committee's report to Council show that the subject has been considered in a broad and realistic fashion, and we strongly support the view that it is impossible for members of Council to be well known to the rank and file of the profession if only one-third are directly elected by members in the Divisions and Branches at home, and it would seem that the remarks by Dr Carter can only serve to confirm our opinion—I am, etc.,

Winchester

RONALD GIBSON

B.M.S. Committee: Correction

SIR,—Paragraph 5 of your report of the special meeting of the G.M.S. Committee (*Supplement*, Jan 29, p 49) does not give the full point of the question as asked by me or of the answers. My question was, "Did the Spens Committee visualize an increase of work equal to that which we are in fact experiencing?" During the answers the chairman (Dr Wand) emphasized the point of the question. Three out of the four replies showed that our present work was much in excess of that foreseen by the Spens Committee as a basis for their report. Dr Carter's reply to the question was to the effect that the Spens Committee's standard of income should be available to the doctor for a normal day's work, leaving him time for recreation, etc. He added these words: "which few, if any, general practitioners seem to enjoy these days." Most of the committee felt that the replies strengthened the argument that while in certain groups the actual Spens figure might be obtained with the present capitation fee it would only be possible by gross overwork, and that therefore Spens was not properly implemented—I am, etc.,

Bristol

WALTER WOOLLEY

POINTS FROM LETTERS

A Doctor's Lot

Dr P. F. O'SHEA writes: "About five weeks ago the local policeman, a robust, healthy specimen of manhood, swaggered into my surgery and demanded a bottle of cod liver oil for his cough. At length I explained to him that cod liver oil was not essential to his cough, and, further, I offered to supply him with a bottle of medicine that would do him more good. Indignantly he left the surgery. Saturday last I received a notification from the Glamorgan Executive Council stating that the said policeman and his wife and two children had transferred 'to another doctor in the E.C. area'."

Doubt in Prescribing

Dr P. R. SAVILE (London, E17) writes: "It is about time that we had some definite guidance as to appliances and drugs allowable under the general medical service. The responsibility should not be left to the individual doctor to decide, for example, whether a sanitary pad is equivalent to a maternity pad. According to a London Executive Council letter in November, 1949, sanitary towels were not supplyable. In spite of this patients continue to come over to us stating that their maternity nurses have sent them, informing them that they are entitled to maternity pads. Thus it is left to our individual interpretation of the problem as to whether a maternity pad is a different species from a sanitary pad. In order to push the Act through, Mr Bevan promised the patient everything for nothing—'You don't have to pay for anything now.' It is about time that he informed the public that that was a slight exaggeration and told them what they couldn't have, not letting the wretched G.P. hold the baby and refuse to allow the patient all that the kind Minister of Health promised."

Association Notices

PROPOSED ALTERATION IN DENBIGH AND FLINT DIVISION

Notice is hereby given by the Council of a proposal to form two Divisions in the place of the present Denbigh and Flint Division as follows:

The East Denbigh and Flint Division the area of the present Denbigh and Flint Division to the east of the Clwydian Range.

The West Denbigh and Flint Division that part of the present Denbigh and Flint Division which lies to the west of the Clwydian Range, with the addition of Colwyn Bay, Old Colwyn, and Rhos-on-Sea.

Any member affected by this proposal and objecting thereto should write to the Secretary of the Association not later than Feb 26, 1949.

CHARLES HILL,
Secretary

PRIZES FOR MEDICAL STUDENTS

The Council of the British Medical Association is prepared to consider the award in 1949 of prizes to medical students for essays submitted in open competition. The subject of the essays for 1949 shall be "The Value of Observation in the Training of the Medical Student." The purpose of these prizes is the promotion of systematic observation among medical students. In awarding the prizes due regard will be given to evidence of personal observation. No study or essay that has previously been published in the medical press or elsewhere will be considered eligible for a prize.

The following prizes are offered:

National Prizes—six, each of the value of £25.

Regional Prizes—as detailed below based on the four Regions of the British Medical Students Association.

London Region, 6 prizes (1 of the value of £15, 5 of the value of £7).

Midland Region, 3 prizes (1 of the value of £15, 2 of the value of £7).

Northern Region, 3 prizes (1 of the value of £15, 2 of the value of £7).

Scottish Region, 5 prizes (1 of the value of £15, 4 of the value of £7).

Any medical student who is a registered member of a medical school in Great Britain or Northern Ireland at the time of submission of the essay is eligible to compete for the prizes. The winners of the National Prizes will be ineligible for the award of a Regional Prize. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final. Should the Council of the Association decide that no essay entered is of sufficient merit, no awards shall be made.

Each essay must be typewritten or written legibly in the English language, and must be unsigned and accompanied by a detachable sheet giving the name of the candidate, his medical school, and his B.M.S.A. Region. Essays must be forwarded so as to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C1, not later than March 31, 1949.

PRIZES FOR NURSES

The Council of the British Medical Association is prepared to consider the award in 1949 of three prizes each of the value of 20 guineas for the best essay and three prizes each of the value of 10 guineas for the second best essay submitted in open competition by each of the following categories of nurses: (i) Pupil nurses; (ii) State registered nurses working in a hospital; (iii) State-registered nurses not working in a hospital—i.e., district nurses, private nurses, etc.

The subjects of the essays for 1949 shall be: category (i), "What discipline do you think necessary in the training of nurses?"; category (ii), "What part of nursing duties can be delegated to others with safety?"; category (iii), "The care of old people in their own homes."

The purpose of these prizes is the promotion of systematic observation among nurses. In awarding the prizes due regard will be given to evidence of personal observation. No essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Nurses who are undergoing training at a

the prolapsed intervertebral disk. In each the critical position is one of flexion of the spine; but the fracture of the vertebral body is produced by forced overflexion, and the prolapse of the intervertebral disk by extension and rotation against resistance. The injury occurs in both at the site of the maximum movement during the maximum pressure. In a typical example, a man is standing in a slightly stooping position when a heavy weight falls on his shoulders, forcing him forwards, overflexing the spine, and causing a crush fracture of the first lumbar vertebra; or, alternatively, the weight misses the man and he stoops, inclining slightly to one side, grasps the weight with both hands and strains to lift it, thus extending and rotating the back, and suffers prolapse of the disk between the fifth lumbar vertebra and the sacrum.

At once it is apparent that the commonest sites for the bone and disk lesions are at opposite ends of the lumbar spine. There is an equally obvious difference in the method of their production. The force producing the bone injury takes the patient by surprise; in the disk injury the force is deliberately produced by voluntary muscular effort.

In those rare instances of fracture of the body of a lumbar vertebra in which the force is applied relatively slowly, as when a man is standing with his back to a stack of bales which collapses, gradually forcing him downwards, the injury is found most frequently in the fourth lumbar vertebra. In this case the man has just had time to brace himself to resist the force before overflexion of the spine has occurred. From this example it will be seen that the lower part of the lumbar spine is vulnerable to both flexion and extension strains when the victim is aware of the traumatizing force, and the upper part of the lumbar spine is vulnerable when he is taken unawares.

If a healthy individual is asked to bend and touch his toes and recover to the erect position, he will be found to maintain regular breathing, probably exhaling during bending and inhaling on straightening the back. But when a man is asked to raise a heavy weight he bends freely but rises against the resistance of the lifted weight. In these circumstances the man usually exhales bending; then there is a preliminary intake of breath, the breath is held at the initiation of the lift, and is released after inertia has been overcome and the movement of extension of the spine has begun.

When the body is braced for a big effort, as lifting a heavy weight, the shoulder girdle is fixed by the external respiratory muscles and the breath is held. The diaphragm is firmly fixed, and this is possible only when the bony attachments of its crura are stationary. The first three lumbar vertebrae are therefore held immobile and movement of the lower back, whether of forced flexion or of voluntary extension, occurs first in the lower lumbar region.

The man who was slowly forced to his knees by the collapsing stack of bales braced himself to resist the overwhelming weight, and, although he succeeded in fixing and therefore preventing overflexion of the first three lumbar vertebrae, suffered fracture of the relatively movable fourth. In the case of the man who attempted to lift the weight, the first three lumbar vertebrae were also held immobile at the initiation of the lifting strain, and the movement of extension occurred between the sacrum and the fourth lumbar vertebra, thus causing maximum pressure on the lowest two disks in the lumbar series.

The mechanism of production of the prolapsed disk as I understand it may be summarized in four stages: (1) Positioning: flexion of the whole lumbar spine with the separation of the posterior contiguous margins of the neighbouring vertebrae. (2) Preparation: fixation of the upper three lumbar vertebrae in flexion. (3) Overcoming

inertia: direct pressure on the lower disks, causing them to bulge slightly beyond the posterior margins of the vertebral bodies. (4) Raising: extension and rotation of the fourth and fifth lumbar vertebral bodies, causing the posterior margin of the bone to nip the bulging disk in a grinding movement with maximum pressure exerted to one side of the midline according to whether the man is inclined to the right or to the left.

It is often very difficult to obtain from a patient a coherent account of the mechanics of his injury. In many cases the workman has "thought back," and his account is no more than an imagination piece. It is essential, therefore, that investigation shall be carried out on the spot and not from the hospital notes. In these notes it is often recorded that the patient strained his back while lifting but never that at the initiation of the movement of lift the spine was in the position not only of flexion but also of slight rotation and lateral flexion, and that in rising the spine was therefore brought back to the straight position by a corkscrew motion.

How to Avoid the Injury

Obviously this leads to the conclusion that there is one particular type of strain that produces the prolapse of an intervertebral disk and, conversely, that it is nonsense to suggest that all heavy work places the nucleus pulposus in jeopardy.

Can the dangerous strain be eliminated or circumvented? Industry already has something to offer by way of solution. When the nature of the work renders back strain particularly prevalent methods have been adopted by custom which have been found to minimize the risks. One of the best examples is that of the coal-miner lifting a tub. The inexperienced man would risk straining his back each time he attempted its performance. Imagine him facing the tub, stooping with back well bent, putting his hands beneath the chassis, straining to lift, and inviting a disk injury. Generations of miners have learned to avoid this risk by the simple expedient of turning the back to the tub and lifting with the hands behind them. In this position the knees can be well flexed. The lumbar spine is held immobile until the actual lift has been initiated by the thigh muscles, and it is only when all the lumbar spine is mobilized by the release of the respiratory muscles that the back is somewhat straightened.

Individuals occasionally learn tricks which afford them some protection from recurrence of their symptoms. A mine-worker (a pan-turner) found that he could avoid pain if all his lifts were made in two stages: he would lift a short distance and then, after a moment's pause, complete the lift. After watching him at this manoeuvre I was able to satisfy myself that the initiation of the lift movement was produced solely at the hip and knee with a completely fixed spinal column and with the breath held, that during the momentary pause breathing restarted, and that full recovery to the erect position took place with even movement of the spinal column, thus distributing any strain up the disks.

But industry's method of selection, by trial and error of suitable work for the "back" case is obviously unsatisfactory, and a scientific approach through careful physiological and functional analysis both of the man and of the machine offers the only practical solution to successful placement. There are three main lines of research.

1. *How to Prevent Threatened Injury in the Performance of a Specific Act.*—The majority of back strains will be avoided if the workman is properly instructed in the art of lifting. Inertia should be overcome and the movement of lifting initiated by the thigh muscles; but if the workman is so placed that he is unable to bend his knees when stooping to grasp the

weight, the lift is initiated through movement at the hip and spinal joints.

2. *How to Avoid the Act which is Calculated to Cause Injury.*—It may not be easy to place in a heavy gang a man wearing the label of light work, but there should not be the same difficulty about placing him in the heavy gang with instructions to the foreman that, although he should do his full share of hard work, he should not be employed in lifting from knee level or lower. Many a man who has suffered a prolapsed intervertebral disk could resume his work at machine or bench without symptoms or fear of relapse if objects which he previously lifted from ground level could be stacked at a height of from two or three feet (60 to 90 cm.).

3. *The Correct Selection of Personnel for the Specific Act.*—At present selection tests are used by the industrial psychologist to determine both adaptability and accident proneness. The anatomist has also made a selection of types that are able to perform certain specialized manœuvres more readily and more efficiently than others. This method of selection was used in

perfection in treatment could be obtained only at the sacrifice of human form.

At the age of 15 a boy had his right hand severely mangled in machinery. The first, second, and fourth fingers were lost at the time, the skin was stripped from the palm and from the remaining half of the third finger, the thumb was split and its metacarpal shared the fate of the others in the hand—being splintered. It was decided to rebuild the hand by plastic surgery. The first stage after cleansing was to bury the hand in the abdominal wall to secure the necessary skin flaps. This was successful, and gradually the process of reconstruction went on. Operation succeeded operation; the stump of the third finger was covered with skin, the second metacarpal was excised, a rotation osteotomy was performed on the fourth metacarpal. Three years went by, during which this boy alternated between the squalor of a city slum and the relative splendour of a lavishly equipped country hospital. Now he possesses something which resembles in appearance the congenital "lobster-claw" hand: one claw is immovable and insensitive, the other

FIG. 1

FIG. 2

FIG. 3

FIG. 1.—Lumbar spine in the act of raising a weight with the breath held, showing upper three lumbar vertebrae fixed in flexion but the fifth lumbar vertebra extended with backward tilt on to the sacrum, tending to nip the disk. FIG. 2.—Same as Fig. 1, centred over the fifth lumbar vertebra. FIG. 3.—The same lumbar spine as Fig. 1, rising to exactly the same position but with the diaphragm free and showing even spacing between the fifth lumbar vertebra and the sacrum.

the war for picking naval anti-aircraft gunners. But no detailed research has yet been undertaken to determine accident proneness in relation to physique and particular function. It has, for instance, been stated that the long thin type of man represents the "disk" type—i.e., that these individuals are prone to prolapse of an intervertebral disk. But this is certainly not borne out in the cases that I have seen, which include tall and short, slim and burly. It is not impossible that some relation may be found between the length of reach and the patient's weight which may have a bearing on the problem. Perhaps a matter of some interest is that in cases of sudden prolapse of an intervertebral disk it is unusual to find x-ray evidence of other changes in the vertebral column. The buttressing of the vertebrae, sometimes spoken of as hypertrophic osteoarthritis, which is found in the spinal columns of many men who have undergone years of heavy work, is seldom seen in these cases.

With "Why" and "How" established, and the foundations well and truly laid, only the span of good will is necessary to bridge the gulf.

The Surgeon's Lost Touch

Surgery's lost touch with industry has been responsible for much unhappiness and much disability by concentrating on local morbidity instead of on general function. The surgeon seeks perfection in treatment, and his first concern is to restore the mutilated human body to conformity with accepted standards. But if he were to keep steadily in his mind that the ultimate aim of treatment is restoration of capacity for work it would sometimes be found that

has feeble and tremulous movement, though so restricted in range as to be quite useless. A sheet of paper placed between the claws flutters away to the ground; a pencil can be thrust between them and held but not grasped. The young man is now attending the physiotherapy department of the city hospital, marking time before readmission to his "country residence" for the next operation in the series.

Now what of the patient himself? He was of fairly good physique, now rather run to fat, but, as his father puts it, he is "no scholar." School, in fact, "did not agree with him," and his entry into industry at the age of 14 marked for him escape from the thralldom of uncomprehended letters. He was eager to declare his manhood, to "muscle in" with his fellows into the strife that was his birthright. Three long years have now gone by, three years of daily contemplation of a pitiful and puny limb, hideous alike in its appearance and in its uselessness. Had that hand been amputated at once a modern prosthesis would have enabled the boy to return to his work in a few weeks, still rejoicing in his strength and brim-full of the enthusiasm of youth. But now what is left but a tale of lost incentive, lost interest, and lost opportunity?

Choice of Treatment

Perhaps the selection of the right form of treatment for the individual patient needs a wider knowledge and a greater experience than any other of the surgeon's duties. One of the most important considerations in restoring working capacity is how long the patient can afford to be away from work without suffering such loss of skill, dexterity, or training as will render him temporarily or permanently

unfit for his pre-accident work although the treatment for his surgical condition has been apparently successfully concluded.

The time factor is of importance in the selection of treatment, but of even greater importance is the patient's own psychology. In the case of the boy with the mutilated hand, a psychological study would have revealed at the outset that his happiness and success in life depend upon his ability to perform simple tasks requiring muscle work but a minimum of reasoning power or intellectual effort. He is not of the type that absorbs instruction easily or is able to profit by lessons in craftsmanship. He belongs essentially to that class of worker designated unskilled labour. Had he been of a different type, of average or more-than-average intellectual capacity, the long years of treatment might have been devoted to preparatory training for some skilled trade or profession, greatly to his and the community's advantage. But for this boy these years were obviously wasted and little could be done to mitigate the bitterness and frustration of thwarted ambition.

After selection of the type of treatment to be given there may still be a variety of different ways of carrying it through. For example, if the patient is suffering from thrombo-angiitis obliterans the selected treatment may be resection of the lumbar sympathetic ganglia, but there are two different methods of surgical approach to the ganglia. First the transperitoneal method through a midline or paramedial abdominal incision; and, secondly, the retroperitoneal method through the loin. This latter is undoubtedly the easier operation to perform, but the risks and difficulties of the former may be justified in certain cases in which section of the loin muscles is likely to interfere with capacity for work. This is but one of many examples in which the surgeon's choice is no more than a guess if he remains in ignorance of industrial conditions.

In theory there can be no difference between the relative importance of treatment for different diseases and different injuries. Each and every one is a challenge to the surgeon, to be met with all the skill and resource at his command. But in practice it has long been the custom to differentiate between major and minor injuries and also to make similar distinction between diseases. The skilled surgeon has tended more and more to restrict his activities to the treatment of selected groups of cases and to delegate to his less experienced colleagues the treatment of minor maladies and minor injuries.

Now this modern surgical perspective is the result of the intrinsic study of morbidity coupled, it is to be feared, with the necessity for the reward for labour. Contact with industry, with its demands for man-power and man-hours, will force the surgeon into a new perspective. The treatment of fractured necks of femurs is not the most important thing in life. In terms of human suffering and human happiness fractured fingers must take pride of place. The fractured femur is a rare occurrence in industry, and if every case became a total loss this would represent only a tithe of the loss and suffering occasioned by the thousands of fractured fingers which occur each year. I am not going to suggest that the fractured femur must be neglected for the fractured phalanx, but that equal care and skill shall be lavished on both. The function of the femur is to sustain the body weight, and the surgeon need seldom modify his technique in treatment to meet industrial requirements. But the function of the finger is far more complicated, and no surgeon can attempt to make the best of his treatment unless he is cognizant of the full industrial requirements of the injured finger. It may be that there are fractures of the proximal and middle phalanges of the little finger with involvement of the first interphalangeal

joint. In such an injury it is not improbable that ankylosis would occur at the damaged joint. If the joint were fixed in extension instead of semiflexion the patient would be handicapped in the performance of such work as required the maximum span of the hand—e.g., use of a lever. But this position of the little finger would not incommode the mannequin, who might be seriously inconvenienced by the little finger fixed in semiflexion because of her inability to put on gloves without splitting them.

In dealing with the choice of treatment and its method of performance I have touched only on the surgeon's immediate responsibilities as they are reflected from industry, but to bring treatment to a successful conclusion much closer contact is necessary. In cases of accidents to the industrial worker it might fairly be stated that *treatment starts before injury*.

The Five Fears

In dealing with the problem of the treatment of the injured workman I must stress the importance of the elimination of the five fears—fear of pain, fear of deformity, fear of financial hardship, fear of industrial degradation, and fear of litigation. The elimination of each one of these fears is the direct concern of the surgeon, although the final responsibility may rest elsewhere. Fear is conceived in ignorance and is dispelled by knowledge. And if propaganda, precept, and example are made to play their proper part much of the fear of injury may be eliminated. If every potential patient is convinced that his particular injury will be the especial care of a surgical specialist, that during the time of his sickness and convalescence he and his family will be properly cared for, that his future will be assured and he will not be lost in that backwater of unwanted men, light work, and that he will not have to spend weary months in straitened circumstances fighting for what he believes to be his right, then indeed treatment will have started before injury.

Co-operation in Treatment

To secure this happy state team work is necessary and may be accomplished only if the yoke of responsibility is shared by the managing director and the hospital consulting surgeon. The armies mobilized in the battle against disease and injury are as much in need of direction from a unified command as ever were the armies engaged in internecine warfare. To this end, then, the influence of the hospital surgeon must pervade every phase of treatment—starting within industry, continuing in home or hospital, and being carried through to its conclusion again in industry. In fact, he must become not only the surgeon in hospital but the surgeon in industry.

The design and equipment of the factory surgery must be a matter of prime concern to the consulting surgeon, whose ultimate responsibility is the treatment of patients who pass through that surgery to hospital. Unless the treatment carried out there is in exact conformity with his ideas of hospital treatment, the surgeon may find himself fighting a rearguard action in the face of infection and deformity instead of continuing the general advance towards full recovery. As a simple example—a guillotine amputation of the pulp of a finger may best be treated by an immediate skin graft, but if the finger has been soaked in strong antiseptic, a familiar form of treatment in many surgeries, the chance of a successful grafting in hospital is very much diminished.

Whereas the factory doctor's consulting-room must be the centre of the teaching and practice of pure industrial medicine, the factory surgery should be an outpost of the hospital. Its personnel, medical officers and nurses, must follow the same routine in treatment as their colleagues in

hospital, and this of course is possible only if the two departments are in constant touch with each other. During the last war the Medical Director of the Ministry of Supply, who was responsible for industrial health in the Government Ordnance Departments, arranged that medical officers and nurses from the factory surgeries should attend courses at a selected hospital in order to keep them in touch with those methods of treatment that were acceptable to the consulting surgeon who, under the Director, was responsible for the treatment of injuries. Similar liaison between the consulting surgeon and the department of the industrial medical officer is essential throughout industry if the optimum treatment is to be afforded to its personnel.

But if the benefits of this close co-operation between the surgery and the hospital are not to be nullified in the case of the injured, still earlier precautions must be taken. Someone must make a stand against the tyranny of tradition, and, as surgeons are not usually lacking in courage, let the consulting surgeon be the first to defy the law and burn the first-aid box.

Rehabilitation

Now after the first stage of surgical treatment is over, further treatment is concentrated on rebuilding the general health and physique of the patient and in restoring and perhaps retraining his muscles to enable them to meet the requirements of his daily work. In many cases the immediate return to pre-accident work is made possible because of the surgeon's particular knowledge of the job and his willingness to modify his treatment to meet its requirements. As a simple example, a waterproof dressing on an injured finger worn during working hours may be sufficient variation from hospital routine. In some cases the later phase of treatment is carried out in the so-called rehabilitation departments of the hospital—or, when the industry is large enough and where the directorate is sufficiently informed, in the rehabilitation department of that industry. In other cases rehabilitation is best given by returning the patient to alternative work under the supervision of the industrial medical officer.

Aim of Treatment

Treatment in a rehabilitation department may take the form of diversional exercises, occupational therapy, or vocational therapy, but the aim of treatment is the same—restoration of the ability to perform certain manoeuvres with the strength, speed, and dexterity with which they were performed before injury. The surgeon will be failing in his duty if he does not inquire as carefully into the nature and duration of these exercises as he would into the circumstances of treatment of the more acute stages of disease. In hospital one all too often sees mixed classes of workmen engaged upon routine exercises, some of which are calculated to retard the recovery of the individual rather than to promote it. The selection and development of types of exercise for particular jobs are as important as is the selection of exercises for particular injuries and diseases. The majority of work is an athletic pursuit, and the prescribing of routine exercises for rehabilitation for all work is as likely to be successful as would be uniform training for a boxer, a professional golfer, and a boat-race crew.

In industry rehabilitation may be carried out in the rehabilitation workshop. This is nearly always a production unit whose output is essential. The unit, however, is run under sheltered workshop conditions and under the direct supervision of the industrial medical officer. It contains machines that are adapted to meet the requirements of specific injuries, and various bench jobs which provide such special exercises as may be prescribed. Here are

machines incorporating in their design special devices for inducing specific joint or muscle action not necessary for normal production.

In general, extremely good results are obtained by the intelligent use of the rehabilitation workshop, but there are many pitfalls. One that is not uncommon is the over-exercising of joints by means of gadgets which necessitate a wider range of movement than is demanded by the patient's normal job. For example, a lever that can be fully operated only by producing eighty or more degrees of dorsiflexion and palmar flexion of the wrist may be ideal in redeveloping suppleness and muscle control in the typist or pianist but is calculated rather to retard recovery in the case of the heavy labourer whose normal wrist excursion may be reduced to some thirty or forty degrees. It must always be remembered that the greater the power demanded of the muscles crossing a joint the less is the range of movement in that joint.

Skilled work is all built up of conditioned reflex actions operating along well-beaten nervous paths. Injury and disease tend to interrupt those paths, and their redevelopment may be facilitated by the choice of suitable exercises calling forth the same co-ordination of eye and brain and limb. Conversely, an exercise that is calculated to cut across the chosen reflex path will delay the recovery of skilled action. The lower the reflex arc in the nervous system the less the fatigue from its accomplishment. It follows, therefore, that maximum benefit with the minimum fatigue will be obtained from exercises which are based upon fundamental reflexes or simple conditioned reflexes. Rhythm must never be neglected, and complicated exercises which call for independent use of each arm and each leg, and which ignore such elementary laws as that of negative successive induction, cause unnecessary mental and physical strain and obscure still further the paths of old-established conditioned reflexes.

Enough has already been written on the advantages of the exercise of selected work over treatment by massage and physiotherapy, but the pendulum must not be allowed to swing to the other extreme: both massage and physiotherapy are invaluable in treatment. But it is still a debatable point whether they belong essentially to the hospital department or whether they should be carried into industry. Undoubtedly selected cases are enabled to continue at work because of a few minutes of special treatment that may be available at their place of employment. An example of this is the wax bath, which helps to loosen up stiff fingers in very cold weather.

Unfortunately it sometimes happens that from the very start of treatment the surgeon knows that it will be impossible to return the patient to his former method of work. In such circumstances it may be possible for him to develop alternative function; and here again nothing but a profound knowledge of industry or industrial conditions will enable the surgeon to plan his treatment ahead.

I have already pointed out one of the risks of exercises which are calculated to produce an extreme range of joint movement, but in selected cases they have a definite place in treatment and in the development of alternative function. An example of this is the production of extra movement in the left wrist of the plasterer who as a result of an old injury has limited extension at the elbow. Extreme wrist movement might enable him to accomplish that smoothness of finish to a ceiling which is usually produced by rotation of the forearm and shoulder with the elbow fully extended.

Further Collaboration

It is now necessary to examine the possibilities of further collaboration. In the case of very large factories employing

thousands of men and women it may be possible to arrange for the surgeon to meet the industrial medical officers and executives regularly there in consultation and see for himself the conditions in which disease and accident arise and follow through the results of his treatment from rehabilitation shop onwards. The majority of industrial workers, however, are employed in small units, and obviously all cannot be visited weekly or even monthly; the surgeon may therefore have to be content with a general knowledge of work and working conditions, but he must always be prepared to make a special investigation when the health of his patient demands it.

As I have intimated earlier, the benefits of the liaison of industry and surgery are not limited to the physical health of the industrial casualties. Together they have much to contribute to the general happiness of mankind, together they may be called upon as the guardians of the public weal.

Of the "five fears" the fear of financial hardship was the first the legislature attempted to relieve. Attempts have now been made to banish the fear of litigation. Last year new workmen's compensation laws were introduced in which the responsibility for the payment of compensation devolved upon the State. When England first introduced workmen's compensation to the world it was a genuine attempt to secure for the injured workman a subsistence allowance during the period in which he remained incapacitated for earning. The payment of his weekly compensation bore a definite relation to his earning capacity and therefore operated as a true, although often insufficient, subsistence allowance. The new workmen's compensation laws ignore the principle of earning capacity and base payment upon the physical standard of the average man. Thus if a workman loses a foot it is calculated that his physical standard has been reduced by 30%, and after a limited number of weeks of benefit he becomes entitled to a pension of 30%. If his work be clerical he may still earn his full pre-accident wage and enjoy the additional pension for his physical injury. But what if he be a stevedore with no prospect of returning to his work? The memory that in former times he would have been entitled to 100% workmen's compensation until such time as his weekly pay-packet came within measurable distance of his old earnings can only plunge him into a more profound state of misery and fear.

I am not proposing to argue whether the principle of workmen's compensation is right or wrong or, indeed, whether it is an anachronism in these days of national insurance; but when the law was being altered it was the duty of the surgeon to point out that, far from allaying the patient's fear, this fear of financial hardship was likely to operate still more effectively in retarding the recovery of his patients. Who but the surgeon can assess that fear, and who but he has the knowledge and the authority to point out the absolute ineffectualness of basing workmen's compensation upon the average man? The "average man," conceived and born in Whitehall, is neither tinker, tailor, soldier, nor sailor; in fact, this average man has never done a day's work in his life, and yet he is set up as the 100% standard by which the casualties of industry are to be judged and pensioned.

The voice of the Royal College of Surgeons should have been raised in protest; it should have thundered at Westminster and reverberated throughout the land. Instead it remained silent. Was it silent through ignorance of industrial conditions, or could it have been that it did not recognize its responsibilities?

I have endeavoured to show that in the proper understanding and performance of his work the surgeon must maintain a close alliance with industry; that his patient's

welfare and happiness are as necessary to the successful conclusion of treatment as is the application of his operative technique; that all the treatment he has to offer is both empirical and incomplete unless he studies to understand the conditions of his patient's work and the physical strains which are involved; that the greatest benefit he has to bestow on his patient is that independence of spirit that can come only with the power to work on equal terms with his fellows; that he has a duty to place his expert knowledge at the disposal of industry for the better organization of its work and the disposal of its man-power; and, finally, that the hospital and the factory are but small parts of the world that mark the sphere of his influence.

I now repeat my question—Is there a place in the hierarchy of specialists for the consulting industrial surgeon? I leave you to supply the answer, remembering that in this age of social service industry is the threshold of social surgery.

5,000 CONSECUTIVE DELIVERIES WITHOUT A MATERNAL DEATH DUE TO PREGNANCY

BY

NORMAN EMBLIN, M.B., F.R.C.S.Ed., M.M.S.A.
M.R.C.O.G.

Consultant Obstetrician and Gynaecologist, Halifax General Hospital; Consultant Obstetrician, Halifax District Nursing Association; Visiting Obstetrician and Gynaecologist, Royal Halifax Infirmary

In the Halifax Municipal Obstetric Service there were between Sept. 12, 1946, and Oct. 5, 1948, 5,000 consecutive deliveries after the twenty-eighth week without a maternal death due to pregnancy. This number includes all women after the twenty-eighth week of pregnancy (a) who were admitted to the Halifax General Hospital from inside or outside the borough, whether to the general medical and surgical wards, the maternity department, or the special unit for the reception of septic cases, and (b) who were delivered in their own homes by the Halifax Domiciliary Service or independent midwives. It will be seen from this that the cases are drawn from the widest possible sources. No emergency has ever been refused admission. In this series there was one death from acute myeloblastic leukaemia and therefore not attributable to pregnancy.

Rufus Thomas (1940a) described the Croydon Obstetric Service and published the magnificent series of 3,144 consecutive deliveries conducted by this service between Jan. 3, 1938, and June 4, 1939, without a maternal death due to pregnancy. In this number there were two deaths—one from pneumococcal pneumonia and therefore not counted as a death due to pregnancy, and the other from post-partum haemorrhage on June 8, 1938 (Thomas, 1940b). This case was considered to be outside the scope of the paper, as the patient had been delivered at home by an independent midwife and admitted after delivery. It was and, so far as I know, remains the largest consecutive number of cases with the lowest maternal mortality ever reported in this country or any other. This was indeed safe obstetrics, and with Croydon as a model and Thomas's work as inspiration it has been my personal ambition and the object and policy of the Halifax General Hospital at least to equal this achievement. Although the Croydon figure has been exceeded in Halifax by 1,856 deliveries it must be remembered that Thomas did not have the help of the later and more effective sulphonamides, blood and

plasma banks, penicillin, or the advantage of the knowledge of the rhesus factor in safeguarding against transfusion accidents. On the other hand, this series began, like his, after a maternal death; but it is still unfinished, as the total number of deliveries before another death occurs has yet to be determined.

At the Royal Halifax Infirmary there is a small maternity unit which deals annually with between 500 and 600 deliveries, mainly booked cases. My association with this institution is a recent one, and as all the infirmary cases are not my sole responsibility they are excluded from the total of 5,000 deliveries described here.

Description of the Service

The Halifax General Hospital has 450 beds—115 for obstetric and 35 for gynaecological cases. The maternity beds are distributed as follows: 80 lying-in, 25 antenatal, and 10 for potentially infected or septic cases. The hospital is a Part I training school, and it must be one of the few maternity departments in the country that have never been seriously short of staff.

Almost all the emergencies from Halifax and a surrounding densely populated industrial area, with a total population of about a quarter of a million, come to the General Hospital. Apart from emergencies, only primigravidae, patients with abnormalities, cases of multiple pregnancy, and those whose home conditions are unsuitable for delivery are admitted. Cases which become septic in the hospital are nursed in the special isolation unit, to which are also admitted septic cases from the domiciliary service and the county area served. There has been no death from puerperal sepsis in any of the admissions to this block since July, 1939.

The Emergency Blood Transfusion Service, for the whole area is based on the General Hospital, where, in addition to the ordinary blood and plasma bank, a supply of group O rhesus-negative blood is always kept. No patient treated by this service has been lost in seven years.

The medical staff of the two departments consists of a registrar, a senior and a junior resident obstetrical officer, and an obstetric house-surgeon. As the obstetrician and gynaecologist in charge, I live within a few minutes of the hospital.

It is one of my main functions to attend at the antenatal clinics at the hospital and at the district home in the town. At these clinics all abnormal cases, whether the departure from the normal is medical or obstetrical, are seen and followed by me throughout the remainder of the pregnancy and labour.

It is a strict rule of the department that I am informed of all emergency admissions, of abnormalities, and of any condition which might even faintly threaten the life of the mother or child. No assistant is allowed to perform any major manipulation without my being present.

The Domiciliary Service.—The Halifax District Nursing Association is a voluntary body responsible for the domiciliary midwifery in the borough. It acts in this as agent for the local authority. The domiciliary service is based on the hostel "Kirby Leas," which is a Part II training school. It is run clinically as an integral part of the hospital, and in this way there is continuity of supervision by me of the difficult and abnormal cases.

The midwives carry "pitocin" and ergometrine to give by injection, and in a case of dire emergency threatening life—e.g., ante-partum or post-partum haemorrhage—they have the right to summon the emergency blood transfusion unit on their own initiative. In other instances the usual practice of summoning the patient's doctor is followed.

There were 795 deliveries, and medical aid was sought 274 times.

Results

During the period under review there were 5,000 deliveries (Table I) and of these 2,498, almost half, were in women pregnant for the first time.

TABLE I.—Showing Total Number of Deliveries, Some Major Complications, and Methods of Delivery

	General Hospital	Domiciliary Service	Total
No. of deliveries	4,205	795	5,000
Primigravidae	2,377	121	2,498
Twins	58	11	69
Forceps	198	10	208
Manual removal of placenta	21	0	21
Caesarean section	98	0	98
Eclampsia	4	0	4
Stillbirths	104	13	117
Neonatal deaths	53	6	59

The forceps deliveries numbered 208—a rate of 4.7% in the hospital and 4.16% in the combined service. Caesarean section was performed 98 times—a rate of 2.33% in the hospital and 1.96% in the total number of deliveries. The placenta was removed manually on only 21 occasions, or once in every 238 deliveries.

There were four cases of eclampsia; only one of them a booked case, and that patient had a solitary fit after delivery. In the three unbooked cases there were nine, three, and four fits respectively. All four babies survived. The booked patient should not have had a fit, as there was ample warning, which was not heeded. I believe that eclampsia is always a preventable disease.

Live Births, Stillbirths, and Neonatal Deaths

There were 69 sets of twins in the 5,000 deliveries. The total number of births was therefore 5,069. There were 117 stillbirths, including all premature, macerated, and grossly abnormal foetuses, giving a stillbirth rate for the service of 23.07 per thousand. Of the 4,952 live births 59 babies died. The neonatal death rate is therefore 11.91.

TABLE II.—Showing Stillbirths and Neonatal Death Rates

	General Hospital	Domiciliary Service	Total	Croydon	National 1946
Total births	4,263	806	5,069	3,178	842,809
Live births	4,159	793	4,952	3,086	819,814
Stillbirths	104	13	117	92	22,915
Neonatal deaths	53	6	59	43	—
Stillbirth rate	24.63	14.88	23.07	28.9	27
Neonatal death rate	12.74	7.56	11.91	13.9	22

Table II shows the total live births and stillbirths together with the stillbirth and neonatal death rates. For comparison the figures for Croydon from Jan. 3, 1938, to June 4, 1939, and those for the whole country for 1946 are included. The latter are the "latest available provisional figures" for a complete year, and have been supplied by the Ministry of Health. The stillbirth rate for the Halifax Municipal

TABLE III.—Showing Some Causes of Stillbirth and Neonatal Death

	Stillbirths			Neonatal Deaths			Total Combined Service
	Gen. Hosp.	Dom. Serv.	Total	Gen. Hosp.	Dom. Serv.	Total	
Dystocia and intracranial haemorrhage	17	2	19	12	2	14	33
Gross foetal abnormality	19	2	21	11	0	11	32
Prematurity	5	0	5	16	1	17	22
Maternal toxæmia	14	1	15	3	0	3	18
Maceration	16	1	17	0	0	0	17
Protrusion of cord	11	1	12	0	0	0	12
Ante-partum haemorrhage	12	0	12	0	0	0	12
Cause unknown	4	6	10	0	1	1	11
Rh. incompatibility	6	0	6	3	0	3	9
Pneumonia	0	0	0	5	1	6	6
Atelectasis	0	0	0	3	1	4	4
Total	104	13	117	53	6	59	176

Service is thus 3.93 lower and the neonatal death rate 10.09 lower than the national rate.

In Table III are set out the principal causes of stillbirths and neonatal deaths, given in their numerical order. The largest number were due to trauma during labour, and these form 18.75% of the total. Gross foetal abnormality (mainly anencephaly, spina bifida, and hydrocephaly) is a very close second with 18.18% of the combined stillbirths and deaths under 1 month. Of the total stillbirths and neonatal deaths 27.84% are accounted for by gross foetal abnormality and maceration, and at the present time it would seem to be impossible to reduce the numbers from these two cases. The greatest field for improvement lies in reducing the number of stillbirths and neonatal deaths caused by trauma, prematurity, and pregnancy "toxaemia."

Treatment of Major Complications

A brief outline of the treatment of the major complications, the choice of sedatives and anaesthetics, and the management of the puerperium is given below.

Ante-partum Haemorrhage.—This condition is treated conservatively until there is a definite indication to intervene. In all cases, when first seen, blood is immediately taken for grouping and cross-matching. Vaginal and rectal examinations and the giving of enemata are strictly forbidden. When it becomes necessary to intervene—e.g., in the case of small recurrent haemorrhage—every patient, no matter how good her general condition, has an intravenous drip started. With blood ready to be given, the patient is examined vaginally under anaesthesia in the operating theatre. If her condition is grave from loss of blood this examination is omitted and caesarean section is performed. In eight years, with a total of 12,830 deliveries in the hospital alone, only one case of ante-partum haemorrhage has been lost, and that death occurred in 1944 from concealed haemorrhage, and therefore does not come into this series.

Placenta Praevia.—This is treated almost always by rupture of the membranes or by caesarean section. The lower-segment operation is the one invariably used. Application of Willett's forceps and plugging with the half-breech are used only on very rare occasions. Packing and the insertion of an intrauterine bag have never been practised.

Accidental Haemorrhage.—This is treated by morphine, "pitocin," plasma or blood transfusion, and rupture of the membranes. Only once in eight years has it been necessary to perform caesarean section and only once to carry out a caesarean hysterectomy for this condition.

Post-partum Haemorrhage.—An attempt is made to prevent third-stage haemorrhage by giving "pitocin," 1 ml. intramuscularly, in the following conditions the moment the child's shoulders are born: prolonged labour, uterine inertia, overdistension of the uterus, delivery under anaesthesia, the presence of fibroids in the uterus, and in any patient who has anaemia. Cases of placenta praevia and accidental haemorrhage receive ergometrine, 0.25 mg. intravenously, as soon as the anterior shoulder has been born. If the placenta is not ready for delivery in half an hour from the birth of the child, or if there is even slightly more than the average amount of bleeding, "pitocin" is given as described above. If the placenta fails to be delivered promptly after the "pitocin" manual removal is carried out. Should the bleeding be heavy and the uterus atonic, ergometrine, 0.25 mg., is given intravenously. So far the intravenous ergometrine has been successful in stopping the bleeding in every case except the one complicated by acute myeloblastic leukaemia. Resuscitative measures can then be undertaken, and the administration of ergometrine does not, in my experience, make a manual removal any more difficult should this be required. Bleeding after the delivery of the placenta is treated by intravenous ergometrine. Intrauterine bags are never used.

Pre-eclampsia and Eclampsia.—Emphasis is placed on abnormal gain in weight as an early sign of pre-eclampsia. On an average the weekly gain should not exceed 8 oz. (225 g.). The maximum normal systolic blood pressure is taken as 120 mm. Hg. and the diastolic as 80 mm. Hg. Oedema is always considered to be pathological, and when, in the absence of pus,

there is albumin even in the smallest amount in the catheter specimen the disease is far advanced. Pre-eclamptic patients are treated by absolute rest in bed in hospital, with a low-sodium and low-protein diet and sedatives. Of the sedatives chloral hydrate and potassium bromide and "nembutal" are the most commonly used. If there is vomiting, sodium phenobarbitone, 3 gr. (0.2 g.), is given intramuscularly. Liberal use is made of 20% glucose solution in water intravenously in severe cases or in those with gross oedema. Ammonium chloride is also given for the latter condition. If the maximum diuresis is to be secured by the concentrated glucose solution a whole litre must be run into the vein in from 30 to 50 minutes. No attempt is made to interrupt the pregnancy unless the mother's condition is deteriorating. By following this rule the incidence of prematurity in these patients has been greatly reduced. I do not believe that chronic nephritis or permanent vascular damage is ever caused by pre-eclampsia or eclampsia, nor is a latent hypertension made manifest or "unmasked" at an earlier age by the pre-eclamptic pregnancy.

I cannot too strongly condemn rupture of the membranes in a patient with a long closed cervix. Rupture of these to induce labour in this condition should be done in only those cases in which the cervix is taken up, is beginning to dilate, and is easily dilatable and soft—a condition which has aptly been described as "ripe." If the cervix is long and closed and the patient's condition is deteriorating rapidly in spite of treatment then caesarean section under local analgesia should be the method of delivery.

Eclampsia is treated by morphine sulphate $\frac{1}{4}$ gr. (32 mg.) and sodium phenobarbitone or "nembutal" intramuscularly. Apart from loosening the clothes, the patient is not undressed or examined in any way until she is heavily under the influence of sedatives. Glucose, 20% solution, is used in all cases. Magnesium sulphate, 50% solution, for intramuscular injection, is kept in reserve for the cases which do not respond: these are exceedingly rare. When there has been no fit for twenty-four hours the patient is examined vaginally, and if the cervix is "ripe" the membranes are ruptured. So far caesarean section has not had to be performed for eclampsia.

Infection.—Of the sulphonamides, sulphadiazine is the drug most often used. Penicillin is reserved for cases that do not respond or for cases that are severe at the onset. As a prophylactic against infection penicillin is given to all cases of manual removal of the placenta, failed forceps, and internal version, and to those in which the membranes have been ruptured for more than twenty-four hours or the labour has been unduly prolonged. If caesarean section is to be performed on an infected or potentially infected patient a million units of penicillin are left in the peritoneal cavity and the drug is given systemically for five days after operation. In urinary infections sulphanilamide is used on account of its free solubility.

Disproportion.—The borderline cases are given a trial labour and if this fails lower-segment caesarean section is performed. In all primigravidae in whom the head is not engaged near term antero-posterior, inlet, lateral, and outlet radiographs of the pelvis are taken. Frequent use is made of lateral x-ray film to follow the course of a trial labour, and these have been most helpful.

Cardiac Disease.—This is treated in mild cases by frequent periods of rest in hospital during the pregnancy. In the severe cases the patient may spend the greater part of the pregnancy in hospital. Caesarean section under local analgesia is reserved for the severest cases. All patients with valvular disease are given penicillin for a week after delivery in an effort to prevent infection, which even in a mild form so often leads to a marked breakdown in the cardiac reserve.

Sedatives and Anaesthetics.—Pethidine in doses of 100 mg. intramuscularly is the routine sedative used. It is often combined with hyoscine hydrobromide 1/150 gr. (0.43 mg.). Since the introduction of pethidine it is rare to have to use morphine. A "heavy" spinal analgesic is used to anaesthetize the perineum if forceps are required for a patient with respiratory or cardiac disease. Spinal analgesia is never used for other forceps deliveries or for caesarean section. In a healthy patient these operations are carried out under general anaesthesia. Local analgesia is employed for caesarean section when indicated by the general condition of the patient.

The Puerperium.—The patients are allowed out of bed on the seventh day and normal cases are discharged on the tenth day. Active movement and breathing exercises are encouraged from the very beginning. Each ward is visited daily by a physio-therapist, who conducts the exercises. During a period of eight years, with 12,830 deliveries, there have been only two deaths from pulmonary embolism.

Discussion

In addition to the series here presented there were from 1944 to 1946 in the General Hospital three separate series, of 1,050, 1,346, and 1,730 deliveries, without a maternal death, and it must be stressed that such results are the outcome of a co-operative effort on the part of the whole staff of both parts of the Municipal Service and of the general practitioners in the area.

Particularly must I lay emphasis on the loyalty and diligence of the resident and nursing staff, who have given service far beyond the power of gold to buy. The excellence of the general administrative arrangements and the ancillary services provided have contributed greatly. Other factors of importance are the large proportion of antenatal beds and the continuity of specialist supervision for abnormal cases.

Of the therapeutic agents, blood, plasma, penicillin, and the sulphonamides have played a great part. It is important to give blood in adequate amount; for example, one greatly exsanguinated woman received 10 pints (5.68 litres), and at one stage two veins were being used at the same time to give the blood under pressure of oxygen. Such treatment has been made possible by the wonderful facilities provided by the Leeds Regional Blood Transfusion Service. Glucose 20% solution, too, has played its part, and Dieckmann (1942) has stated that the proper use of hypertonic glucose solution in pregnancy is one of the outstanding accomplishments of modern obstetrics. In third-stage and post-partum haemorrhage, ergometrine, given intravenously, has proved life-saving and deserves to rank in importance in obstetrics with penicillin.

These potent remedies together with modern methods of anaesthesia are great advances, but the most important single factor is the skill and ready availability of the senior staff to deal personally with abnormalities. It can be shown that the maternal mortality rate in the cases delivered in the General Hospital is lower than the rate for the borough as a whole.

In the last ten years the borough deliveries numbered 14,833, with 43 maternal deaths—a rate of 2.89. In the same period the General Hospital, dealing with almost all the emergencies from inside and outside the borough, had 14,324 deliveries with 24 deaths, giving a rate of 1.67. And it is noteworthy that part of this decade was before the introduction of blood banks and penicillin, and that as late as 1946 (the last year for which complete figures are available) the national rate was 1.43.

In the Ministry of Health Report (1937) Halifax was shown to be the county borough with the blackest maternal mortality record in the country. It occupied an almost equally unenviable position in the R.C.O.G. Report (1944), in which for the years 1939 to 1942 it was placed seventh in a list of county boroughs with the highest rate in England and Wales. This, however, was largely due to the eleven maternal deaths in Halifax in 1940; only two of these occurred in the General Hospital and one on the Domiciliary Service.

It is true, then, to say that the high rate for the borough in a list of county boroughs with the highest rate in deaths in the General Hospital or on the Domiciliary Service, where in the same ten-year period there were 4,389 deliveries with the death of only one woman.

Summary and Conclusions

Along the lines suggested by the Royal College of Obstetricians and Gynaecologists (1944) we have attempted to bring about the integration of the hospital, antenatal, domiciliary, and specialist services in the Halifax Municipal Obstetric Organization.

Between Sept. 12, 1946, and Oct. 5, 1948, there were 5,000 deliveries after the twenty-eighth week without a maternal death due to pregnancy.

The stillbirth rate in the series was 23.07 and the neonatal death rate 11.91.

A brief summary of the treatment of some major complications has been given.

The Halifax General Hospital has a large proportion of cases from the county area, and therefore the number of its deliveries in the last decade almost equals the total ascribed to the borough.

In this ten-year period the maternal mortality rate in the General Hospital was 1.67; in the Halifax Borough it was 2.89.

The belief is expressed that the most important single factor in reducing maternal mortality is the provision of skilled staff to deal with abnormalities.

This series began after a maternal death from pulmonary embolism and continues without a maternal death attributable to pregnancy at the time of writing (Oct. 6, 1948).

I am grateful to the M.O.H. for Halifax, Dr. G. C. F. Roe, for permission to publish these results and for the statistics relating to the Borough. My thanks are due to Mr. H. I. Deitch, medical superintendent and surgeon to the General Hospital, for his great help in many difficult cases and for encouraging the development of the maternity department of the hospital.

A STATISTICAL AND CLINICAL REVIEW OF 107 CASES OF ECTOPIC GESTATION

BY

J. S. MACVINE, M.B., B.S., F.R.C.S.Ed., M.R.C.O.G.

AND

D. H. LEES, M.B., Ch.B., F.R.C.S.Ed., M.R.C.O.G.

(From the Central Middlesex Hospital, London)

Ectopic pregnancy is a condition encountered by all clinicians engaged in general medical and surgical practice. The management usually falls to the gynaecologist, but the problem of the differential diagnosis concerns all, and in many cases the operative treatment has to be done by the general surgeon.

Keeping that in mind, we have undertaken a survey of all cases of ectopic pregnancy occurring in a busy municipal hospital over a ten-year period. The findings are instructive in showing that the question of aetiology has not finally been settled. It is, however, in the sphere of diagnosis that we believe the value of such a survey lies. The various symptoms and physical signs are evaluated in the light of the case records and an attempt is made to ascribe to each its true place and importance. The treatment and general results are also considered.

Despite the enormous literature on ectopic gestation, few recent surveys of this type have been made, and nearly

all of these were in America. Several will be referred to subsequently.

Present Series

The cases in this series numbered 107. The average age of the patients was 29.9 years. This is in accordance with previously noted figures. The ages varied between 20 and 42. On an average the patients had had 1.25 pregnancies, and 34% of all the pregnancies ended in abortion—a rather high figure.

The time interval between marriage and ectopic pregnancy, or between the ectopic and the last intrauterine pregnancy, averaged 5.8 years. This finding agrees with the figures of Woodhouse (1940), Ware and Winn (1941), Marchetti *et al.* (1946), and MacFarlane and Sparling (1946). It supports the view that sterile or relatively sterile women are more prone to ectopic gestation. Whether this is a result of pelvic inflammation is another matter, and will be dealt with more fully later.

Right- and left-sided tubal pregnancy occurred in 55 and 50 cases respectively. There is thus no real preponderance of the right side as has been suggested by Mayo and Strassmann (1938) and by Nucci (1946). The theory is attractive, as the right side is that more likely to be involved following lesions of the appendix. Ovarian pregnancy occurred in 2 (1.87%) of the 107 cases. The usually quoted figure is 1%. There were six cases of recurrent ectopic gestation—an incidence of 5.6%. Nucci's figure is 6.6%.

At operation it is extremely difficult to say where the ovum originally embedded. This is particularly so if there is an old rupture with haematocele formation or if a tubal abortion is in progress. In this series fully 50% were definitely ampullary, about 10% were fimbrial, and a further 20% might have been either of these. Isthmic forms made up 10% of the total, and at least two of the most severe type were interstitial.

Causation of Extrauterine Pregnancy

We have considered the causation under six headings, really working on a basis of Novak's (1947) classification, and we attempted to evaluate this as a criterion.

1. *Pelvic Inflammation.*—A history of anything possibly classifiable as genital infection was obtained in only seven cases. In 18 cases there was a history of one or more previous abortions, most of which took place some years before the ectopic pregnancy, and in no case was an abortion followed by prolonged subsequent uterine. No patient gave a history of puerperal sepsis, but it is realized that some degree of puerperal or post-abortive morbidity may have been overlooked or forgotten. In several cases there was a normal delivery in the interval from the last abortion.

The operative findings were carefully recorded and gave the following information. In a total of eight cases there were some peritubal adhesions, but a certain proportion of these dated from the first blood leakage and were associated with the haematocele present. Hydrosalpinx was found in one case, and bilateral tubal occlusion following an old ileo-caecal tuberculous process in another. A chronically inflamed appendix was encountered at one operation for right tubal pregnancy.

These figures would suggest that pelvic inflammatory disease, particularly gonorrhoea, but also post-abortive and puerperal sepsis, has been much overrated as a cause or predisposing factor in ectopic pregnancy.

Many of the authorities are absolutely convinced of its importance, and Dougal (1937) estimates pelvic infection as a cause in 50% of cases. Novak (1947) supports this view, and Woodhouse (1940) puts the figure as high as 65.8%. These latter figures are based on a definite history, or showing evidence of pelvic inflammation at operation. MacFarlane and Sparling (1946) give a history of previous abortion in 32.7% of their cases, and say that this is of unquestionable importance in the causation of ectopic pregnancy. They had a total of 17.2%

proved cases of pelvic infection. Marchetti *et al.* (1946) do not agree about the role of infection, and say that in most instances the aetiology is not clear. Dodds (1940) considered that in his series the possible predisposing causes were unconvincing.

2. *Previous Pelvic Operations.*—It does seem that previous operations on the pelvis may have a bearing, and it would be reasonable to expect conditions complicated by infection or peritonitis to be most prolific of ectopic gestation. In this series six patients had had appendicectomy, the appendix being ruptured, with local peritonitis, in one case. Six patients had had ectopic pregnancies, two had had ovariectomies, and two had had pelvic operations for tuberculous glands. Thus 16 of the 107 cases had previously had an operation. Farrell and Scheffey (1943) found that 26% of their cases had had previous abdominal operations. Dodds's (1940) figures for previous pelvic operations would work out at 20%.

3. *Congenital Abnormalities.*—The importance of congenital abnormalities or defects must be very difficult to estimate, and would be small.

4. *External Factors Altering the Lumen of the Tube.*—Alteration in calibre of the Fallopian tube and distortion due to external factors would seem to be a more likely cause. In this series we found the following:

Cystic or enlarged ovaries noted (not corpus luteum)	16 cases
Fimbrial or parovarian cysts	3 "
Uterine fibroids in a position to obstruct the affected tube	1 case
Tubal fibroid on uterine side of ectopic sac	1 "
Endometrioma of broad ligament	1 "

The enlarged or cystic ovaries were usually studded with a series of follicular cysts. These were seldom larger than $\frac{1}{2}$ in. (1.9 cm.) in diameter, but occasionally needed surgical attention. Many cases were not carefully examined, so that the incidence of these cysts is not fully recorded. The latter were the severe intraperitoneal rupture cases. Certain cases show this relationship very clearly. We have seen a tubal abortion in which the ectopic sac extended medially to a kink in the Fallopian tube caused by the pressure of a simple ovarian cyst the size of a pullet's egg.

5. *External Transmigration of the Ovum.*—One case afforded evidence of this. The ovary had previously been removed on the affected side and the tube on the opposite side.

6. *Tubal Spasm.*—This is held to be a very important factor, but we have not been able to collect any helpful information. In only two cases had a tubal insufflation been done—in both some time previously. A history of attempted abortion was given in three or four cases, but quite what the true incidence of this would be we do not know. From the very high rate of induced abortion in this particular district it would seem reasonable to regard it as a possible factor.

Diagnosis in Relation to Symptomatology

The proportion of cases in which particular symptoms appeared are as follows:

Abdominal pain	98%
Vomiting associated with the pain	41%
Faintness	42%
Anomalous uterine "bleeding"	76%
Amenorrhoea (including late or overdue period in a woman normally of regular cycle)	71%
Shoulder pain (including pain in the upper arm and in the upper chest or pectoral region)	37%
Bladder symptoms	26%
Rectal symptoms	16%

It will be seen that pain is by far the most reliable and constant symptom. It may be of any type, depending on the pathology. Pain sufficient to cause vomiting is a common description, and there is no doubt that it is a help in diagnosis. Nausea is not included in this estimate. The incidence of shoulder pain is higher than has previously been reported, and is a valuable diagnostic guide. The importance of bladder symptoms in diagnosis has never been fully recognized. These usually take the form of dysuria and frequency due to bladder irritation. In many of these cases urinary investigations were done and failed to reveal

any evidence of infection. Rectal irritation was evidenced as pain on defaecation, sacral pain, or diarrhoea.

There is general agreement on the importance of abdominal pain, amenorrhoea, and anomalous bleeding as the important triad. MacFarlane and Sparling (1946) found nausea and vomiting due to pain in 30% of their cases, while 35.4% complained of faintness due to pain; in 11.8% there were bladder symptoms. Marchetti *et al.* (1946) did not find nausea and vomiting with any regularity, although they noted faintness due to pain in 29.1% of cases and shoulder pain in 8.5%. Dodds (1940) reports that seven of his 19 acute cases had shoulder pain.

Diagnosis in Relation to Pathological Types

Cases of ectopic pregnancy may come under one's care at any stage of the pathological process, and the findings differ so much that some attempt at classification must be made. We have taken as a basis that of Dougal (1937). Briefly, the four types are: (a) where the ovum is still in the tube and there is little or no haemorrhage into the abdomen; (b) tubal rupture or abortion with diffuse intraperitoneal haemorrhage; (c) tubal rupture or abortion with encysted haemorrhage; and (d) advanced ectopic pregnancy. We have taken (a), (b), and (c) and termed them Types 1, 2, and 3, respectively. Our Type 1 group includes cases with a somewhat more generous blood leakage, while under Type 3 are included the subacute cases with haematocoele formation, even if not actually encysted.

Diagnosis in Relation to Physical Signs

The physical findings are considered in relation to the pathological type of ectopic gestation. Taking them in order, the incidence was as follows:

Type 1 (29 Cases)

Tenderness in iliac fossa or suprapubically ..	89%
Softening of the cervix ..	89%
Tender swelling felt per vaginam ..	82%
Uterine enlargement ..	62%
Pain on moving the cervix ..	58%
Breast activity ..	53%
Pulsation felt in fornices ..	28%

Type 2 (48 Cases)

Tender on abdominal examination ..	100%
Pain on vaginal examination (done in 39 cases only) ..	97%
Fullness felt on vaginal examination (ditto) ..	87%
Evidence of internal haemorrhage ..	85%
Distended abdomen ..	77%
Patient prostrate ..	56%
Abdominal resistance or guarding ..	50%
Free fluid in abdomen ..	41%
Tube palpable ..	Nil

Type 3 (28 Cases)

Mass felt on vaginal examination (with or without general anaesthesia) ..	100%
Tender on vaginal examination ..	96%
Abdomen tender on examination ..	89%
Softening of the cervix ..	88%
Pain on moving the cervix ..	84%
Uterus enlarged ..	65%
Uterus felt separate from the swelling ..	61%
Breast activity ..	54%
Patient pale in appearance ..	54%
Abdomen distended ..	50%
Patient apparently ill ..	46%
Abdominal guarding or resistance ..	32%
General feeling of tumour on abdominal examination ..	32%

Thus it is seen that all types, and particularly Type 2, have abdominal tenderness.

Pain on vaginal examination is the other common finding. This is usually elicited in the posterior or lateral fornix. A tender swelling is the usual accompaniment in Type 1, a generalized fullness is all that can be made out in Type 2, while a vague mass in the cul-de-sac is the common finding in Type 3.

Softening of the cervix is a very important diagnostic point and occurs in nearly 90% of Type 1 and Type 3

cases; it is of less diagnostic importance in Type 2, and is often overlooked in the obvious cases of that group. Pain on moving the cervix with the finger would appear to be a less reliable finding than tenderness in the fornices.

The presence of breast activity was a great diagnostic help in the less acute cases. Where there had been frank rupture and diagnosis was obvious it was surprising how often the breasts were not examined or at least no record of their condition was made.

Enlargement of the uterus was noted in 60-65% of Type 1 and Type 3 cases; it cannot be demonstrated in Type 2 cases.

In Type 2 there is very often evidence of internal haemorrhage, the abdomen is rather distended, and free fluid may be demonstrated. There is some degree of resistance or guarding in about half of the cases.

In Type 3 the patient often looks pale or ill. The average pulse rate was worked out for this group, and was 104 per minute. The temperature averaged between 99 and 100° F. (37.2 and 37.8° C.), with evening readings as high as 101° F. (38.3° C.). There may be some distension of the abdomen, but a tumour is rarely felt, and rigidity is also rare. In fully half of the cases the uterus was felt separate from the pelvic mass on vaginal examination.

The other signs, the blood investigations, pregnancy diagnosis tests, and curettage are usually too slow and unwieldy to be of value. We must admit, however, that the pathologist's report led to our exploring one of the cases.

Reference to the literature shows no great disagreement on these matters. Some authors stress the importance of one sign and some favour another. It must be remembered that diagnostic criteria are comparable only when a similar stage of the pathological process is encountered. There is a tendency both here and in America to discount the value of colpotomy, curettage, and haematological investigations in diagnosis.

Treatment

Blood Transfusion.—It has been our custom to give blood at once to the Type 2 cases admitted in a state of collapse. The theatre is meantime prepared and the patient is taken there with the blood-drip transfusion running. This is continued during the operation, and afterwards for as long as is necessary. We do not agree with those who say that blood should not be given before the operation is begun. Neither do we agree that operation should be postponed (in Type 2) till the general condition is greatly improved. The number of cases requiring blood transfusion was 41, and the average amount of blood given to each transfused patient was 1,080 ml. A reaction in the form of raised temperature and slight jaundice was observed in one case, but was quickly overcome. In nearly every case group O stored blood was given.

Williams and Corbit (1944), investigating 101 deaths from ectopic pregnancy, found that only 37 of the patients had received blood transfusion. Only four had more than one transfusion, although the time interval could have allowed of others. MacFarlane and Sparling (1946) transfused 57% of their cases, while Marchetti *et al.* (1946) transfused 42.16% of theirs.

Operative Treatment.—It was Lawson Tait (1888) who thoroughly established the treatment of ectopic pregnancy. The treatment is surgical and the earlier it is done the better. We think that if the patient is exsanguine and shocked it is reasonable to start blood replacement at once, with the other resuscitation measures. So far as the actual operation is concerned, it is advisable to do the least possible when the patient is in a serious condition. The affected tube is removed and haemostasis secured. In this series the following operations were done:

Salpingectomy	77
Salpingo-oophorectomy (one bilateral)	24
Oophorectomy	2
Removal of sac of pregnancy only	1
Partial salpingectomy	2
Laparotomy only	1
Cysts necessitating ovariectomy or cystectomy	7

Thus it will be seen that salpingectomy is usually sufficient, and in common with others we advocate total salpingectomy. The risk of recurrence in the same tube is otherwise said to be high. It is mainly in Type 3 cases that salpingo-oophorectomy is necessary, and is due to involvement of the ovary in the haematocoele to such an extent that it cannot be dissected clear. Ovariectomy is necessary in cases of ovarian pregnancy. The comparatively large number of cases with some cystic involvement of the ovaries will be noted, and was mentioned previously.

The above procedure is fairly standard. Mayo and Strassmann (1938) stress the importance of conservative measures. Dodds (1940) preserves the ovaries wherever possible, while Dougal's (1927) figures show that he was less conservative in treatment. There has apparently been a tendency in America to do operations for other abnormalities discovered at the time of dealing with the ectopic pregnancy. Williams and Corbit's (1944) investigations of mortality figures have led them to condemn the doing of multiple non-essential operations.

There was one death in this series, giving a mortality rate of 0.93%.

The number of days in hospital before operation was taken as a method of assessing the accuracy of diagnosis. All the days the patient spent in hospital before the operation are counted. The average time was 2.8 days. Marchetti *et al.* (1946) record that 27% of their cases were operated on within 24 hours of admission, while 70.2% had operation within 48 hours.

Summary

A series of 107 consecutive ectopic pregnancies occurring over a ten-year period is reviewed. The findings are compared with those of recent reviews.

In respect of aetiology we find little support for the time-honoured view that previous pelvic inflammation is all-important. We believe that previous operations on the pelvis are a predisposing factor, and we are strongly of the view that extratubal factors causing alterations in calibre of the lumen are an important cause.

Diagnosis is considered in relation to symptomatology, pathological types, and physical findings. Our figures show that carefully taken histories reveal a very much higher incidence of helpful diagnostic symptoms than has previously been reported. For example, we find a high percentage of those patients complaining of vomiting and faintness due to pain, of shoulder pain, and of irritative bladder symptoms.

The treatment of these cases has been orthodox in every way. We attach particular importance to the free use of blood pre-operatively, without delaying the operation once the diagnosis has been made.

ENDOGENOUS GAS GANGRENE COMPLICATING CARCINOMA OF COLON

REPORT OF A CASE

BY

A. L. WYMAN, M.D., M.R.C.P.

Late Assistant Medical Officer, Lambeth Hospital

Clostridium welchii is commonly present in the human intestine. Its pathogenic qualities are well known, yet it is rare for gas gangrene to complicate diseases or surgery of the alimentary canal unless introduced from outside. Rare though it is, this complication has long been recognized. Welch (1900) gave three examples of primary emphysematous gangrene of the abdominal wall which he believed started from the intestine. Greeley (1918) described two cases of "idiopathic *Bacillus aerogenes capsulatus* infection." In one of his patients the blood culture was positive three months before death. In the case described below, the organism was grown from the blood 17 days before death.

Several writers have reported endogenous gas gangrene arising after operation, especially after appendicectomy (Eckhoff, 1930; Gamble, 1935; Johnson, 1936; Smith and Zimring, 1939; Breslin, 1940). Jennings (1931) found that 90% of cultures made from the contents of the lumen of appendices removed at operation grew *Cl. welchii*.

Gas gangrene may arise even when no operation has taken place. Gordon (1936) treated conservatively an appendix abscess which ruptured and formed a pelvic abscess. Gas gangrene of the right thigh developed, and at necropsy it was seen that the peritoneum and fascia overlying the iliopsoas muscle had been eroded and that the gas gangrene had spread down this muscle to the lower limb.

It may also arise after typhoid ulceration and tuberculous ulceration of the small intestine (Knapper, 1929; Galiani and Balaguer, 1946). Dawson and Hardy (1948) reported emphysematous cellulitis of the left thigh resulting from diverticulitis.

Case Report

The patient, a man aged 65, had all his teeth extracted in September, 1947. A few days afterwards he felt some pain in the lower abdomen on the left side. He had to strain to defaecate, and when he was successful the pain disappeared. Later he felt as though his bowels were not completely emptied after defaecation, and the pain was not completely relieved. The motions were soft, without blood or slime. His appetite was poor and he had lost weight. There was no nausea or vomiting, and urination was normal. He was admitted to hospital on Nov. 14, having been febrile for four days. He had had an operation for bilateral inguinal hernia in 1915.

On examination he was flushed and looked ill. The temperature was 102° F. (38.9° C.), pulse 80, and respiration 20. The gums were healthy, the throat clean, and the tongue furred. Some petechiae were seen on the floor of the mouth. The abdomen was tumid and there was a tender indurated area with slight erythema above the left Poupert's ligament. The hernia scars were healthy. Neither spleen nor liver was felt. Intestinal movements were audible. Rectal examination revealed nothing abnormal. There was a slight degree of kyphoscoliosis of the spine but no local tenderness. The patient kept his hips flexed, and there was some pain in the left hip on external rotation. A blood culture was taken before any treatment was given.

The next day the reddening of the skin was more apparent in a line 6-8 in. (15-20 cm.) long, about 1 in. (2.5 cm.) above and parallel to the left inguinal ligament. He was very tender near the left anterior-superior iliac spine. Penicillin and sulphamezathine were given.

In the course of the next few days the inflammation spread down the thigh, chiefly on its anterior and medial aspects, as far as the knee. The skin was red and brawny, with a small necrotic patch in the mid-thigh. A fine crepitation in the region of the anterior-superior spine was palpable. On Nov. 19 Mr. W. K. Targett incised the thigh. "With a large aspirating needle, foul-smelling greyish-brown pus was obtained fairly superficially in the thigh (inner side). An incision in the same area opened a superficial 'space' containing gas and more pus. This was lined with greyish necrotic material. A drain was inserted. A second incision lower down was made. More gas and pus were found. The whole process was more like a generalized infiltration than true abscess." Anti-gas-gangrene serum was given.

After the operation the patient's general condition improved a little, but locally there was an extension of the inflammation below the knee, with effusion in that joint and oedema of the leg. A black bulla was present in the thigh. Soon a necrotic area joined the two incisions. Subcutaneous crepitus could be felt in the upper and outer part of the thigh (Fig. 1).

FIG. 1.—Wound in left thigh and extent of inflammation one week after operation

On Nov. 27 a fresh spontaneous sinus appeared near the knee posteriorly. The following day a morbilliform rash attributed to the sulphamezathine appeared on the right thigh and then spread generally. By Dec. 1 he looked worse; he became drowsy and dyspnoeic, and died the next day.

Investigations.—Nov. 15:—blood culture: growth of *Cl. welchii*; blood count: Hb, 90%; red cells, 5,140,000, white cells, 17,000 (polymorphs 81%). Nov. 17:—radiography: chest normal; spine and pelvis, no destructive bone changes seen, jaws edentulous. Nov. 19:—swab from wound: direct film—many Gram-positive and Gram-negative bacilli and cocci; aerobic culture gave a growth of non-haemolytic streptococci, coliform bacilli, and Gram-positive sporing bacilli. Anaerobic culture: no anaerobes isolated. Nov. 25:—radiography of left thigh: considerable gas present in the soft tissues, consistent with gas gangrene (Fig. 2).

FIG. 2.—Radiograph of thigh showing gas in soft tissues

Post-mortem Examination.—A fungating carcinoma of the descending colon, 2 by 3 cm., was found just below the anterior-superior spine of the ilium. The carcinoma extended three-quarters of the way round the bowel and constricted the lumen but did not occlude it. There was a small stercoral ulcer 1 cm. proximal to the growth. The carcinoma was adherent to the psoas sheath and there was a track from the bowel into the psoas sheath, the contents of which were gangrenous. The superficial tissues over Poupart's ligament were also necrotic. Sections showed an anaplastic spheroidal-cell carcinoma of the colon with a marked trabecular formation. It had eroded through all layers of the gut wall. The muscle showed fragmentation with much oedema and hyaline degeneration. There were numerous clumps of *Cl. welchii* in the spleen. All swabs taken grew *Cl. welchii*.

Summary

An account is given of a patient with carcinoma of the colon presenting as a gas gangrene of the left thigh. The infection had spread from the intestine to the psoas muscle by means of a track connecting the carcinoma to the psoas sheath.

Similar examples of gas gangrene resulting from diseases of the bowel are quoted from the literature.

I am greatly indebted to Mr. W. K. Targett for the surgical treatment of the patient, and to Dr J. Hewlett and Dr G. Vincent for the pathological investigations

ENTERITIS NECROTICANS DUE TO CLOSTRIDIUM WELCHII TYPE F

BY

J. ZEISSLER, M.D.

AND

L. RASSFELD-STERMBERG

(From the Bacteriological Institute, General Hospital, Hamburg-Altona)

In Hamburg on Oct. 8, 1946, Beckermann and Laas gave an account of a number of cases of a severe illness, often fatal, due to a necrotic inflammation of several areas of the intestine, especially in the jejunum. The onset was acute, with very severe pain and slight rigidity, mostly in the left lower abdomen, without obvious guarding. Vomiting and profuse diarrhoea resulted in general dehydration; within a few days extreme circulatory collapse occurred, with general cyanosis. Increased blood urea, low blood chloride, indicanæmia, and indicanuria were often demonstrable. The temperature was slightly raised (up to 38° C.), the blood picture showed a moderate leucocytosis with a marked shift to the left, and the blood sedimentation rate was increased. Surgical and post-mortem examination showed a diffuse sloughing enteritis of the jejunum, ileum, and colon, beginning in the terminal part of the duodenum or the first loop of the jejunum. The most severe lesions were tube-like areas of necrosed mucosa a foot or more in

length. The folds of the mucosa were rigid and thick: large necroses in the upper part of the jejunum were associated with great swelling of the whole inner wall of the intestine. Microscopically the necroses were simple, often extending through the submucosa to the muscle layer, and retained much of the original architecture of the intestine. No significant organisms were recovered from blood, stools, or urine, and no rational therapy could be suggested.

Jeckeln (1947, 1948), in Lübeck, described a similar apparently new disease, called "darmbrand," and suggested that it might be due to a toxin. At the same meeting Ruppert stated that the prognosis was uncertain and the mortality probably 40%. Siegmund (1948) states that the surface of the necrosed mucosa contains many bacteria, especially Gram-positive bacilli.

Heine (1947) refers to very acute cases, one patient dying within twelve hours of the appearance of symptoms. In these he found only redness and swelling of the mucosa, but no necrosis, and is somewhat doubtful that they are cases of enteritis necroticans. As, however, his cases showed oedema of the intestinal wall without leucocytic infiltration it is possible that they were due to bacterial toxins and might be regarded as hyperacute cases of the disease.

Schütz (1948) claimed that the organism responsible for darmbrand was an obligate anaerobe "very closely related to *B. welchii* type A, if not identical with it." Guinea-pigs injected subcutaneously or intramuscularly with cultures of his organisms in Tarozzi broth developed typical gas gangrene. Injection of liquid cultures into the duodenum of guinea-pigs led, especially if alkali was injected at the same time, to oedema of the duodenal wall, necrosis of the mucosa, and even perforations of the lower ileum and caecum. Schütz made no attempt to determine the type of *Cl. welchii* to which his organism belonged. This typing is, however, extremely important, as *Cl. welchii* type A is normally present in the ileum and colon, and may ascend into the upper part of the intestine if other pathological changes occur there. Moreover, the toxins produced by the different types of *Cl. welchii* require entirely different antitoxins to neutralize them, so that any rational therapy must to this extent depend on exact identification.

Lezius (1948), apparently impressed by Schütz's findings, treated his cases with a sulphonamid ("marbadal," a derivative of "marfanil") effective against *Cl. welchii* type A and also with a polyvalent gas-gangrene serum containing *Cl. welchii* α -antitoxin but no β -antitoxin.

Between September, 1946, and January, 1948, we received material from cases of enteritis necroticans from our colleagues (Aschenbrenner, Baniecki, Kuster, Laas, Loeweneck, and Rabl) for bacteriological examination: three loops of intestine removed by operation, specimens of intestine from eight post-mortem cases, and stool from a living patient in whom the diagnosis was well established clinically and by x-ray examination. From all these materials an organism closely resembling *Cl. welchii* was isolated.

Morphology

Its rods are rather thicker and usually longer than those of *Cl. welchii* type A, often growing into long filaments and forming clostridia and chains of spindles like *Cl. butyricum* and *Cl. gigas* (*Cl. oedematiens* type B) (Figs. 1-3). In surface colonies swollen forms and clostridia are to be found mainly in rough colonies, whereas the smooth colonies consist almost entirely of smooth single rods, somewhat thicker than those of *Cl. welchii* type A. The rough colonies may closely resemble those of *Cl. oedematiens*; this, however,

causes no difficulty in identification, because *Cl. oedematiens* is peritrichous, whereas the organism isolated from cases of enteritis necroticans has no flagella. These morphological differences are, however, not consistent enough for use as discriminants, but the abundant development of rough colonies in surface culture and their marked difference

FIG. 1.—*Cl. welchii* type F, elongated forms ($\times 1,500$)

FIG. 2.—*Cl. welchii* type F, clostridial forms ($\times 1,500$)

FIG. 3.—*Cl. welchii* type F, chains of spindles ($\times 1,500$)

from the normal smooth colony of *Cl. welchii* type A at useful indications of the presence of the new organism (Figs. 4-7).

A decisive difference between the organism isolated from cases of enteritis necroticans and *Cl. welchii* type A is the high thermal resistance of its spores. Though in nature *Cl. welchii* type A forms rather resistant spores (surviving 100°C . up to 90 minutes), spores produced in the usual liver broth or brain pulp seldom resist boiling for more than ten minutes. In comparison all strains of the new organism grown on similar media produced spores resistant to boiling for from one to four hours. This high resistance of spores produced in culture is not only an important criterion for the identification of the new bacillus but leads readily to its detection and isolation.

For the opportunity of comparing the new bacillus with the other types of *Cl. welchii* we are indebted to Lieutenant-Colonel F. Buckland, Lieutenant-Colonel R. J. Townshend, Dr. G. M. Findlay, and Dr. S. T. Cowan (List Institute) and to Dr. C. L. Oakley (Wellcome Physiologic Research Laboratories), who arranged for a supply of strains of all the types. Examinations showed that none of the types so far described—B, C, D, E (Bosworth, 194) produced spores capable of withstanding boiling for more than fifteen minutes.

It is therefore possible to differentiate the new bacillus isolated from cases of enteritis necroticans morphologically and culturally from all types of *Cl. welchii* so far described and we therefore propose for it the name *Cl. welchii* type F.

All cultures used in this investigation were separated from other organisms by repeated boiling of sporing cultures and were derived from single cells obtained by micro-manipulation

Toxicology and Pathogenicity

Toxicology—As no suitable sera were available in Germany for the discrimination of the types of *Cl welchii* eight strains of the new organism were sent to Dr. C L Oakley

the lamb-dysentery bacillus, which like *Cl welchii* type F produces β -toxin. It seems probable, therefore, that the damage to the intestine in enteritis necroticans is due to the β -toxin of *Cl welchii* type F

Sensitivity—*In vitro* tests showed that *Cl welchii* type F is inhibited by 10 units but not by 1 unit of penicillin per ml, that it fails to grow in "badional" (sulphamylthiourea) 1 in 156; that it is remarkably sensitive to "marfanil" (sulphamylon, *US*), "marbadal" (a derivative of marfanil),

FIG 4—*Cl welchii* type F, one rough, one smooth colony ($\times 25$)

FIG 5—*Cl welchii* type F, mature smooth colony ($\times 25$)

FIG 6—*Cl welchii* type F, rough colony, with characteristic threadlike outgrowths ($\times 25$)

who reported that they produced traces of *Cl welchii* α -toxin, considerable quantities of β -toxin, and some γ -toxin. No δ -, ϵ -, θ -, κ -, or λ -toxin was produced. Oakley's findings that the main toxin is β shows that treatment with *Cl welchii* type A serum would be of no value, as this serum contains no β -antitoxin, and that for any hope of success in treatment serum containing *Cl welchii* β -antitoxin would be essential.

Pathogenicity—Intramuscular injection of cultures of *Cl welchii* type F into guinea-pigs leads to the production of a glassy gelatinous or blood-stained oedema similar to that produced by injection of *Cl welchii* type B. Death occurs rapidly—something in our experience never seen in other anaerobic infections. Intravenous injection of culture usually led to death in a few minutes. Though feeding *Cl welchii* type F cultures to guinea pigs did not cause enteritis, injection of 5 ml of a one-day-old culture of *Cl welchii* type F into the lumen of the guinea-pig's intestine led to the development of an enteritis histologically

and "supronal" (a mixture of sulphamerazine and marbadal), which all inhibit its growth at 1 in 10,000 and that sulphadiazine does not affect its growth at all.

THE TOXINS OF *CL. WELCHII* TYPE F

BY

C. L. OAKLEY, M.D., B.Sc.

Eight cultures of a type of *Cl welchii* isolated by Professor Zeissler from cases of enteritis necroticans have so far been examined. They were subcultured into meat broth within 24 hours of arrival, and after appropriate subculture were tested for toxin production by growing them for times varying from 5 to 16 hours in 5-litre quantities of meat broth plus concentrated papain digest of horse meat with a small amount of meat particles, 0.5% sterile glucose was added immediately before inoculation. The cultures were passed through sterile paper pulps to clarify them and finally sterilized by filtration through Seitz filters. In some instances filtrates were precipitated by saturation with ammonium sulphate and the cake so produced dried.

Examination for Toxins (cf. Oakley, 1943)

Lecithovitellin Tests (Macfarlane, Oakley, and Anderson, 1941)—Filtrates from all strains except Z6 and Z8 produced opalescence on incubation for one hour at 37°C with egg-yolk emulsion; this opalescence could be inhibited by adding to the filtrate *Cl welchii* α -antitoxin free from other known antitoxins, but was never marked enough to serve as indicator in a full serological investigation.

FIG 7—*Cl welchii* type F, rough colony with wavy outgrowths (resembling *Cl oedematis* type A) ($\times 25$)

and bacteriologically very similar to that observed in enteritis necroticans in the first days of illness (Professor Laas) and very similar to the enteritis and localized ulceration long known to occur in lambs and foals infected with

Haemolytic Tests.—Filtrates from all strains except Z6 and Z8 produced slight haemolysis of sheep red cells. This haemolysis was inhibited by *Cl. welchii* α -antitoxin and, like the opalescence produced in egg-yolk emulsions, is probably due to *Cl. welchii* α -toxin.

Necrotizing Tests.—All filtrates except those from Z6 and Z8 produced a necrotic reaction on intracutaneous injection into guinea-pigs. This reaction is readily inhibited by sera containing *Cl. welchii* β -antitoxin, and serum values can be determined against a standard, using the production of a small area of necrosis (approximately 2 by 2 mm.) as standard indicating effect. Table I shows that sera

TABLE I.—Serum Values against *Cl. welchii* Type F Filtrates in Necrotizing Tests to Show Presence of β -toxin

R.7365 ..	1,350	1,650	1,300	1,300

neutralize the necrotizing activity of these filtrates in proportion to this β -antitoxin content: the necrotic lesion is therefore probably due to β -toxin.

Lethal Tests.—All filtrates (except those from Z6 and Z8) produced rapid death in mice on intravenous injection. The lethal property is completely neutralized by sera containing *Cl. welchii* β -antitoxin, but serum-value tests show that both β - and γ -toxins are present in the filtrates. Thus the majority of sera examined give the same value in lethal tests as in necrotizing tests (Table II), and confirm the presence of β -toxin; a few, however, though giving the β value in necrotizing tests, give a much lower value in lethal tests, suggesting the presence of γ -toxin in the filtrates. No evidence could be obtained in either lethal or necrotizing tests of the presence of ϵ -toxin.

TABLE II.—Serum Values against *Cl. welchii* Type F Filtrates in Lethal Tests to Show Presence of β - and γ -toxins

present organism does not agree exactly with any type so far described. By the classical methods of Wilsdon (1931–32–33) it would be diagnosed as type C, but its failure to produce κ or δ , or to produce much α , or to ferment glycerol to any marked extent is good evidence against this view. It most closely resembles strains of *Cl. welchii* type I that have lost their power to produce ϵ -toxin; but in view of the high consistency in the strains derived from enteritis necroticans and Zeissler's observation (confirmed in these laboratories) that culture spores of these organisms are much more resistant to heat than those of *Cl. welchii* type B, I consider it reasonable to regard it as a new type—*Cl. welchii* type F.

Antitoxins in Convalescent Sera.—Of six sera examined from persons convalescent from clinical enteritis necroticans three contained about 0.2 unit of *Cl. welchii* β -antitoxin per ml.; the others contained less than this amount. No *Cl. welchii* α - or ϵ -antitoxin could be demonstrated.

I should like to express my thanks to Miss H. E. Ross and to Mr. H. Proom for subculturing these materials and for supplying me with much useful information; and to thank Miss Ross for providing all the culture filtrates.

RECOVERY OF *CL. WELCHII* TYPE F FROM PRESERVED CULTURES

BY

C. DIECKMANN, M.D.

(From the Bacteriological Institute, General Hospital, Hamburg Altona)

Sixty-three strains identified as *Cl. welchii*, preserved in Professor Zeissler's collection of anaerobes, were inoculated into liver broth; from the growth five test-tubes containing brain pulp were inoculated. After two days' incubation in Zeissler's anaerobic jar at 37° C. and three days' at room temperature the test-tubes were boiled in Koch's stean pot at 100° C. for 5, 60, 120, 180, and 240 minutes and cooled immediately in cold water. From the material so treated 0.5 ml. was transferred to test-tubes containing liver broth and incubated in the anaerobic jar for two days at 37° C.

Of the 63 strains tested only two survived boiling for as long as 5 minutes—one survived 120 and the other 18 minutes. Both had the characters of *Cl. welchii* type I. Both were recovered from war wounds of German soldiers on the Russian front in 1943; one (Ru 62) was the only pathogenic organism recovered; the other (Ru 72) was associated with *Cl. sordellii*, *Cl. oedematiens maligni gracili*, *Cl. tetani*, and *Cl. putrificus verrucosus*.

ORIGIN OF *CL. WELCHII* TYPE F INFECTION

BY

E. HAIN, M.D.

From the Bacteriological Institute, General Hospital, Hamburg (Altona)

The following case throws some light on the origin of *Cl. welchii* type F infection in man

Case Report

A man aged 71, never ill previously but with a rather poor digestion for the last few years, ate with some friends a meal consisting of tinned rabbit, tinned fat giblets, and green cabbage. A few hours later he fell ill with abdominal discomfort and frequent vomiting, later he developed abdominal pain, and during the night passed about twenty watery stools. Increasing exhaustion and low blood pressure developed, and he was admitted to hospital next morning.

His notes state that he was a well-developed rather fat man, apathetic, weak-looking, pale, with some cyanosis of his extremities, his pulse was scarcely perceptible, his blood pressure very low. His abdomen was slightly distended, he felt no pain, but was tender in the right epigastrium. His temperature was 39° C. His blood picture showed a polymorphonuclear leucocytosis with a marked shift to the left, the blood sedimentation rate was increased. Electrocardiography revealed evidence of recent cardiac infarction.

Passage of frequent blood-stained watery stools led to further dehydration and impairment of the circulation, restorative measures and treatment with "resulfon" had no effect, surgical treatment was considered hopeless. The patient died about 40 hours after the onset of the symptoms.

At necropsy the clinical diagnosis of enteritis necroticans was confirmed, there was a necrotic inflammation of the jejunum, most marked in its upper part and decreasing in severity along its length. Several smaller ulcers were present in the ileum and rectum.

Two persons who shared the meal with the patient fell ill soon after it with slight sickness, and one passed a single watery stool. Both recovered in twenty-four hours without calling in a doctor.

Bacteriological Examination—Full bacteriological examinations were made of the remnants of food left from the meal of stools from the patient and from those who had shared the meal with him, and of the contents of a loop of the patient's intestine obtained post mortem. The green cabbage and stool from one of the friends yielded no significant pathogen, from all the other samples *Cl. welchii* type F was readily isolated by the following technique.

(1) **Stool**—Samples of stool the size of a pea were placed in test-tubes containing sterile broth and boiled at 100° C. in a steam-pot for 60 minutes. This acted as a first screen for selecting organisms with resistant spores. About one-fifth of the boiled material was inoculated with liver broth and both tubes were incubated in the anaerobic jar for 16 hours at 37° C. If no growth occurred in the liver broth it was reinoculated from the broth tube.

(2) **Other Materials**—These were inoculated into 100–500 ml of brain pulp and incubated for three to five days. From this material 0.5 ml was inoculated into fresh brain pulp and the five tubes so inoculated were boiled for 60, 90, 120, 180 and 240 minutes.

Then by repeated subculture from liquid to solid media, and from solid to liquid, with frequent boiling of sporing cultures, pure cultures were obtained and tested for action on gelatin, sugars, and alcohols, and for pathogenicity to guinea-pigs.

Comment

The food used in the meal had been prepared from home-bred rabbits butchered about three weeks before and used immediately. The tins were closed and boiled for

two hours in a water bath. When the tins were opened and the meat prepared for food three weeks later it appeared wholesome in appearance and odour. Notwithstanding this, three persons who ate it sickened; one of these died, and from the stools of two of them and from the meat *Cl. welchii* type F was recovered. It is clear that the usual method of sterilizing meat by boiling for two hours will not suffice if it is contaminated with this organism.

I have to thank Dr Aschenbrenner for the clinical notes and Dr Baniecki for the post-mortem record.

ON THE OCCURRENCE OF *CL. WELCHII* TYPE F IN NORMAL STOOLS

BY

E. HAIN, M.D.

In an investigation on the occurrence of *Cl. welchii* type F in the normal intestine, 108 stools derived from persons not suffering from enteritis necroticans were examined for the presence of this organism. The results are shown in Tables IV and V.

As the patients were a reasonable cross-section of the inhabitants of Hamburg, I feel that the figures show that about one-sixth of the normal persons in Hamburg during the winter of 1947–8 carried *Cl. welchii* type F in their stools. The strains recovered are, however, much less pathogenic for animals than those isolated from cases of enteritis necroticans. Most of the guinea-pigs who received

TABLE V—Results Arranged According to the Origin of Stools Yielding *Cl. welchii* Type F on Culture

<i>Cl. welchii</i> Type F	Origin of Material					Total
	Cases of Typhoid and Paratyphoid Fever	Cases of Diarrhoea and Dyspepsia Suspected of Typhoid Paratyphoid or Dysentery	Cases of Surgical and Skin Diseases	Cases of Internal Disease	Personnel of Camp Kitchen	
Positive	2	2	3	9	3	19
Negative	11	11	18	47	2	89
Total	13	13	21	56	5	108

injections into the thigh of pure cultures of the organisms from normal stools would have recovered without treatment had they not been killed on the second or fourth day after injection.

The pathological changes produced in the injected animals (glassy gelatinous oedema of the subcutaneous tissues) were qualitatively similar to those produced by the more virulent strains but far less severe.

Further research will be necessary before it is possible to show whether carriers are of any importance in the epidemiology of enteritis necroticans.

Medical Memoranda

Cl. welchii Infection of the Eye

Panophthalmitis caused by *Clostridium welchii* is a rare condition, and the following case is presented for addition to the literature. Walker (1938) reviewed twelve cases, and in 1946 Capus reported on one.

CASE HISTORY

An apprentice plumber aged 15 sustained an injury to his right eye at 2.30 p.m. on Sept. 27, 1948, while using a steel chisel on a brick wall. A fragment of the metal broke off and became lodged in his eye. He was taken to the local hospital, where removal of the foreign body was attempted without success. Penicillin, 200,000 units, was given approximately two and a half hours after the injury was received. He was transferred to the Aberdeen Royal Infirmary, arriving there about 2.30 a.m. on the 28th. On admission he was examined and given 300,000 units of penicillin, this being repeated three-hourly.

Examination revealed the following: the pupil of the right eye was very small; the iris pattern was indistinct and the anterior chamber shallow; an incision of the cornea had been made running from 6 to 9 o'clock, and there was a wedge-shaped foreign body lying about 8 to 9 o'clock, with some bleeding beside it; no red reflex was seen. At 9 a.m. he was re-examined. The cornea was found to be bright and there was no obvious sign of infection. The foreign body appeared to be lying about 10 mm. behind the cornea. Twelve hours later the eye was septic and proptosed, so that enucleation became necessary. This was carried out by Dr. J. Mutch. During the operation gas and blood-stained pus escaped freely. Afterwards the socket was dusted with penicillin. When the eyeball was examined it was found to be distended with gas and pus. There was retinal detachment.

Post-operative recovery was rapid and the patient was discharged on Oct. 11 with a clean, well-healed socket.

Bacteriological Investigation.—The contents of the eyeball showed pus cells, diphtheroids, and Gram-positive rods. A loopful of pus was inoculated into Robertson's meat broth and litmus milk. A typical "stormy fermentation" reaction was obtained from the latter. A subculture plated on horse-blood agar and incubated anaerobically for 48 hours gave a heavy pure growth of *Cl. welchii*. The colonies were haemolytic. The Nagler reaction was positive. A broth culture filtrate made from the plated colonies was lethal to mice, 0.2 ml. of an 18-hour culture causing them to die within three to four hours.

COMMENTARY

Apart from the rarity of this type of case, it is interesting that panophthalmitis should ensue in spite of the early administration of penicillin in large amounts. It has been shown experimentally (von Sallmann, 1944) in rabbits that before a panophthalmitis can be produced *Cl. welchii* has to be introduced into either the lens or the vitreous, and as penicillin fails to diffuse into the latter in any appreciable quantity this would probably account for its failure to arrest infection in this case.

I am much indebted to Drs. L'v and Mutch for permission to use their case notes.

Dislocation of Hip-joint at "Rugger"

Dislocation of the hip is uncommon even in rough games, and occurs only as a result of great violence. It is seen in young people whose femur is strong and resilient enough to escape fracture of the neck. Nevertheless, in the course of twenty years of a busy undergraduate practice between the wars, among the many college and university players at Cambridge no case had been encountered at rugby football until the one now reported.

CASE HISTORY

On Jan. 29, 1948, I was called to a college ground where the captain of the home side was lying in agony, in drenching rain, while two friends held his right lower limb with the hip and knee joints flexed, and the thigh abducted, as requested by the patient. The slightest movement provoked cries of pain. Morphine was given at once. A brief examination indicated a diagnosis of dislocation of the hip-joint, and, not without difficulty and anguish, the patient

was placed in the waiting ambulance, his friends maintaining their attendance during the journey to the local nursing-home.

Reduction.—He was anaesthetized immediately with thiopentone, and the diagnosis of dorsal dislocation was confirmed. We were prepared for a long pull in a very muscular ex-Service man, but trial was first made of simple manipulation. The hip and knee were flexed, followed by simple movements of rotation while in this position. The head of the femur suddenly slipped easily back with a click into the acetabulum, and full movements were at once restored.

In view of the rarity of this accident at rugger, it is of interest to see how it happened.

Patient's Story.—The patient, a hefty centre three-quarter, stated that the ground was very wet, making swerving and even running at speed very difficult. "I had the ball and was running at medium pace, when a wing-forward tackled me from behind. I resisted the tackle, which stopped my forward momentum. As I continued to resist, the pressure was downwards and backwards, with my knees bent, and the strain taken in my hips. Gradually my legs bent wider and I fell sitting as they shot out in front. I think the joint was 'out' then—I certainly felt a great deal of pain—but as I sat down a second opponent kicked and swung the right leg across to the left. My leg remained sticking up in the air, held up by my own hand and subsequently by others. Any movement was agonizing."

From the above account it would seem that, with the feet everted to try to retain a grip on the slippery ground, the limbs were steadily forced into flexion while in a position of wide adduction, until the head of the femur became dislocated on to the dorsum ilii. The subsequent kick, swinging from without inwards, would merely serve to aggravate the displacement and to accentuate the pain.

Massage and infra-red rays were given daily at first. On the sixth day the patient got up on crutches and was bearing some weight, but he had pain on "swivelling." He returned to his rooms at college that day. On the seventh day he went up and down a flight of stairs to the w.c. On the tenth day he walked 1½ miles (2.4 km) and next day he rode a bicycle. After two months he played golf, tennis, and squash. Recovery was uneventful.

R. SALISBURY WOODS, M.D., F.R.C.S.

Diphtheritic Vaginitis

The following report of a case of leucorrhoea due to an infection by the Klebs-Loeffler bacillus is worth recording because of its rarity.

CASE HISTORY

A married woman aged 33 was referred to the gynaecological outpatients department because of increasing leucorrhoea. This had been present in a minor degree for about a year, but during the past month had become profuse and offensive. Stovarsol pessary, prescribed by her doctor, had had little if any effect. She had had one pregnancy three years previously, which was terminated after a long labour by an incision of the cervix and a forceps delivery. Menstruation was regular. Her general health was excellent and she had had no serious illnesses in the past. No history of contact with a diphtheritic case could be obtained.

Examination of the vagina revealed a profuse watery dirty-coloured discharge, which had the odour encountered in the breath of patients suffering from faucial diphtheria. After cleansing the vagina by swabbing, the cervix was seen to be covered by large superficial discrete ulcers, the surface consisting of a greyish exudate which was adherent and could be removed only in small portions by very firm swabbing, leaving a raw bleeding area. The whole vagina was reddened and inflamed, and the upper two-thirds contained numerous pin-head ulcers. Examination did not cause undue discomfort. Specimens of the discharge sent for laboratory investigation revealed the presence of a pathogenic strain of the diphtheria bacillus.

The patient was transferred to the isolation hospital, where she was given a single intramuscular dose of 40,000 units of antidiphtheria serum, and penicillin 100,000 units twice daily for three days. This treatment caused an almost immediate improvement of the vaginitis, discharge being absent after one week. Three further specimens from the vagina, at weekly intervals, gave negative results for the diphtheria bacillus. Examination of the vagina and cervix one month after she was first seen showed a normal mucous membrane with no sign of the previous ulceration.

COMMENT

Diphtheritic infection of the vagina is rare, but if it can present a clinical picture which is so typical that it can cause no difficulties in diagnosis, provided the possibility of infection is borne in mind.

I wish to thank Mr. H. A. Hamilton, gynaecologist, Gloucestershire Royal Infirmary, for permission to describe this case.

North Gloucestershire Hospital Group.

Reviews

PROBLEMS OF FERTILITY

Problems of Fertility in General Practice. By Margaret Hadley Jackson, M.B., B.S., D.R.C.O.G., Joan Malleon, M.B., B.S., J.C.S., M.R.C.O.G., Kenneth Walker, M.B., F.R.C.S., by Sir Eardley Holland, M.D., F.R.C.S., D.G. (Pp. 255; illustrated. 17s. 6d.) Medical Books, 1948.

In the *British Medical Journal* of Feb. 14, 1948 (p. 294), under the heading "What the Medical Practitioner Wants to Know," Dr. R. T. Bevan analysed the 2,018 subjects which appeared in the "Any Questions?" column during the years 1943-6. He drew attention to the fact that in addition to those which were classified as gynaecological a large proportion of the questions were concerned with sex problems, implying that this aspect of medicine is not only inadequately taught in our medical schools but one on which it is not easy to obtain information from the books ordinarily found in a doctor's library. The remedy is now at hand in this volume published under the auspices of the Family Planning Association, and it is safe to say that most of the questions would never have been sent had this book been available to the inquirers.

Its individuality and its attractiveness depend in large measure on its wide, although essentially practical, view of human fertility. Thus it includes discussion of normal and subnormal fertility, abortion, contraception, and a small section on eugenics. The references to some of the most difficult clinical problems such as impotence, frigidity, premarital examination, artificial insemination, and eugenic sterilization are particularly helpful. There are, too, some useful hints on the terms which may be used when discussing these intimate matters with patients. The authors describe in admirable detail those procedures which can be regarded as coming within the province of the general practitioner, and say enough of the others to enable the family doctor to interpret, and to assess the value of, the results of investigations carried out by a consultant. Moreover, it would appear that great care has been taken to keep the account reasonable and free from those extravagant and unscientific claims which so often mar writings on these subjects. So much is this true that it is surprising that the description of the traditional treatment of threatened and habitual abortion with progesterone is not qualified in the way which recent work would appear to demand. It might also be remarked that it is questionable whether oestrogens merit a place in the treatment of trichomonas vaginitis in women whose ovarian function is normal; this is particularly true in cases of infertility, because the dose recommended is one which, according to another chapter, is sufficient to suppress ovulation. By and large, however, the authors are to be congratulated on a most interesting as well as informative work, which will undoubtedly have a wide appeal.

T. N. A. JEFFCOATE.

HERNIA

Hernia. Anatomy, Etiology, Symptoms, Diagnosis, Differential Diagnosis, Prognosis and Treatment. By Leigh F. Watson, M.D., F.I.C.S. Third edition, enlarged and thoroughly revised. (Pp. 732; 323 illustrations by Helen Lorraine, Willard C. Shepard, Ralph Sweet. £3 7s. 6d.) London: Henry Kimpton, 1948.

A comprehensive monograph such as Leigh Watson's, which is now in its third edition, is useful because there is so much divergence of opinion about the most suitable operation for each variety of hernia and because the methods used by surgeons of experience for the radical cure of hernia differ so considerably. This was brought out at a meeting of Service and E.M.S. consultants during the recent war. While for inguinal hernia one advocated the Bassini operation even in a young child, others preferred in young subjects to remove the sac and disturb the inguinal canal as little as possible, and in cases in which there was an agreed indication to reinforce the canal the methods practised were many and diverse. Such

experience should be enough to convince anyone of the difficulty of standardizing surgical practice and the need from time to time to review it in detail.

This edition is much better than the two which preceded it, and we are pleased to note that certain suggestions made in our review of the second edition have been adopted, notably the addition of an index of authors and a reduction of the space devoted to describing injection treatment. The account of this treatment is in better perspective in this edition; it has but a small place—some surgeons might deny it even this—in surgery to-day. We might hazard an opinion that in future editions even less space will be given to discussing sclerosing therapy than the 70-odd pages still allotted to it. Lateral anastomosis (p. 81) is not often a good procedure, and end-to-end junction should in our opinion be performed by suturing and be given pride of place over all forms of anastomosis. Is Moynihan's absorbable bobbin still popular, as stated on page 79? It is certainly not in Britain; and the Murphy button illustrated a little further on is surely only of interest as evidence of the ingenuity of its inventor and because of its place in the history of intestinal anastomosis.

The author describes well the rarer varieties of hernia such as the obturator, lumbar, and perineal types, and the illustrations, which are all good, are plentiful throughout, as are the historical references. We should like to have seen Parry of Glasgow's name mentioned in association with Lotheissen of Vienna in connexion with the repair of femoral hernia by the inguinal canal route. The author might also have referred more to Halsted's important papers, which give a clear description of his operation for inguinal hernia by transplantation of the cord; after complete extirpation of the sac the canal is closed in by a double-breasted overlap of the external oblique behind the transplanted and now superficial cord. This operation has all the advantages of the fascial suturing procedures and is applicable to both the oblique and direct varieties of inguinal hernia. The many methods described may confuse the young surgeon, but they will probably be fascinating reading to the more experienced practitioner, serving to remind him how from time to time what are apparently innovations are in reality a reintroduction of methods which have previously been described, adopted for a time, and abandoned. Such may be said for most of the flap types of reinforcement in which pieces of rectus sheath or fascia lata are turned out of their normal position to reinforce the canal. Dr. Watson begins the first chapter with a quotation from Galen, "No great and perfect work is ever accomplished as a single effort, or receives its final polish from one instrument"—a salutary observation which may well be applicable to the various editions of this book, of which the present one is by a wide margin the best yet.

LAMBERT ROGERS.

OPERATIVE GYNAECOLOGY

Operative Gynecology. By Harry Sturgeon Crossen, M.D., and Robert James Crossen, M.D. Sixth edition, entirely reset and revised. (Pp. 999; 1,334 illustrations, including 30 in colour. £3 15s.) London: Henry Kimpton, 1948.

The last edition of this book was published in 1938, and the new edition will be very welcome, for textbooks of gynaecological surgery are relatively few. The criticisms of the previous editions were directed in the main towards the length of the book and what some regarded as unnecessary details about relatively unimportant operations. The illustrations were always admired and the subject matter was clearly expressed and fairly easy to follow.

In the new edition much of what was regarded as redundant has been removed. The book is now of a convenient size, and taken as a whole it can be regarded as the leading textbook of gynaecological surgery in the English tongue. It is easy to find minor faults in a book of 900 pages. The arrangement of the subject matter is not altogether satisfactory, for much of the last 150 pages could have been introduced at the beginning, and perhaps the authors might have paid less attention to conditions which are not strictly gynaecological. On the other hand, their account of the methods of dealing with injury to the ureter is admirable and in excellent detail. They are clearly worried by the high frequency of malignant disease

of the female genital tract and pay much attention to the practical means of preventing it. Furthermore, they discuss the methods of treating carcinoma of the uterus almost at the beginning of the book. A point of some interest is that they do not seem to have such great enthusiasm for using drugs of the sulphonamide group as is customary in Britain.

The book will be generally welcomed, for it gives a full account of gynaecological surgery, and the manner in which the subject is presented is vigorous and stimulating.

WILFRED SHAW.

MEDICINE FOR NURSES

Introduction to Medical Science. By Gulli Lindh Muller, M.D., and Dorothy E. Dawes, R.N., M.A. Second edition. (Pp. 580; illustrated. 20s.) Philadelphia and London: W. B. Saunders Company. 1948.

The authors of this book, a pathologist and a nurse, provide in comparatively small space a comprehensive outline of pathology, clinical pathology, and public health for nurses. A historical introduction leads on to a systematic account of modern medical science. Sections on the causes of disease and the bodily changes they induce are followed by an account of how diseases may be diagnosed and treated. The last section is on their prevention. The authors omit little. For example, in sixteen pages on the pathology of tumours they describe some thirty different types of neoplasm, with six illustrations. In five pages on renal-function tests they find room to describe the principles and techniques of the concentration and dilution, the dye-excretion, and the various clearance tests, including those with inulin and diodrast. They mention the more important wartime advances in medicine, including even the uses of plasma fractions and parenteral amino-acid therapy.

So much detailed and up-to-date information compressed into so short a space makes the book rather dull reading, and the young student nurse for whom it is intended would find it difficult to see the wood for the trees. The book is "to serve as an overview of medical science prior to her services on the wards," but the order of the exposition, though logical, would probably make the book unintelligible to anyone without clinical experience. The first chapter is no easier than the last, and to guide the student through the many new concepts and unfamiliar terms there is only a glossary to help her. Even this may fail her, as in, for example: "Atopy, Condition of being sensitive to an atopen or a substance to which an allergic person is sensitive"; or "Gonadotropic hormone, Hormone of the sex glands." The style, which is careless and inelegant, increases the difficulty of understanding the text.

Only a physiological approach can make modern medicine intelligible to the novice, and there is need for an introductory book in which disease states and their natural histories are interpreted in terms of disordered structure and function. The authors of this work do not attempt this. Its use in Britain will be chiefly as a book of reference for ward sisters and others responsible for teaching nurses. In America it presumably caters for a syllabus that our nursing curriculum fortunately does not include.

L. P. R. FOURMAN.

In *An Approach to Social Medicine* (Baillière, Tindall and Cox; 15s.) Dr. John D. Kershaw discusses the development of a particular attitude towards medicine and society. While every good practitioner is actively concerned with the development of medicine in relation to social life, too few have accepted the challenge that medicine (among other agencies) must actively influence social activities in the interests of human well-being. Dr. Kershaw reviews the structure of society in order to evaluate its disorders and then discusses the relation of the major branches of medicine to social activities. Finally he considers some of the health problems created by society. Social medicine is a philosophy of health, and in this chapter he deals appropriately with the human and social instruments of that philosophy. This practical work is recommended both to medical men and to those who claim to be intelligent responsible citizens; it is to this audience that the author appeals. Succinct and necessarily dogmatic, it will interest many readers, and for the more inquiring there is an excellent bibliography.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Les Entretiens de Bichat 1948: Chirurgie - Spécialités. Edited by Dr. Petit-Dutaillis. (Pp. 374. 800 francs.) Paris: L'Expansion Scientifique. 1948.

Short articles on a wide variety of surgical topics, including ophthalmology and gynaecology.

Les Entretiens de Bichat 1948: Médecine. Edited by G. Laroche and L. Justin-Besançon. (Pp. 390. 800 francs.) Paris: L'Expansion Scientifique. 1948.

Short articles on many aspects of clinical medicine

Sexualhormontherapie. By E. Tscherné. (Pp. 231. 75 Sch.) Vienna: Wilhelm Maudrich. 1948.

A monograph on the physiology and therapeutic uses of sex hormones.

Diseases of the Nose and Throat. By the late Sir St. Clair Thomson and V. E. Negus, M.S., F.R.C.S. 5th ed. (Pp. 100-70s.) London: Cassell. 1948.

This edition includes new material on inflammatory complication and their treatment by chemotherapy and antibiotics.

Les Diastases. By P. Fleury and J. Courtois. (Pp. 216. 150 francs.) Paris: Armand Colin. 1948.

An introduction for students and non-specialists.

Marriage Counselling. By D. R. Mace, M.A., B.Sc., Ph.D. (Pp. 167. 8s.) London: J. and A. Churchill. 1948.

An account of the work done by marriage guidance councils

Péan. By R. Didier. (Pp. 242. 800 francs.) Paris: Maloine 1948.

A biographical study of the French surgeon.

Techniques in Physiotherapy. Edited by F. L. Greenhill S.R.N., M.C.S.P., T.H.T., and others. (Pp. 222. 12s. 6d.) London: Hodder and Stoughton. 1948.

Intended for the practising physiotherapist.

La Dénutrition de Guerre. By E. F. Simonart. (Pp. 262. No price.) Paris: Maloine. 1948.

A study of the effects of starvation in Belgium during the war

A Textbook of Biochemistry. By R. J. Williams, Ph.D., D.Sc. 2nd ed. (Pp. 533. 25s.) London: Macmillan. 1948.

Intended specially for medical students.

Measurements of the Public Health. By F. A. E. Crew, M.D. D.Sc., Ph.D., F.R.C.P.Ed., F.R.S. (Pp. 243. 18s.) London: Oliver and Boyd. 1948.

Essays on such topics as population, illegitimacy, the sex ratio, marriage, and the biology of death.

Annual Review of Microbiology. Edited by C. E. Clifton, and others. Vol. 2. (Pp. 532. 36s.) London: H. K. Lewis. 1948.

Includes reviews of the nature of antibodies, the metabolism of malaria parasites, and the pathogenic streptococci.

Der praktische Arzt und die Tuberkulose. By H. Ulrich. (Pp. 165. M.7.50.) Berlin: Springer. 1948.

A guide to tuberculosis for the general practitioner.

The Medical Clinics of North America. (Pp. 288. No price.) London: W. B. Saunders. 1948.

A symposium on recent advances in gynaecology and obstetrics.

The Trent and I Go Wandering By. By R. G. Hogarth, C.B.E., D.L., J.P., F.R.C.S., Hon. LL.D.Ed. (Pp. 144. 12s. 6d.) Nottingham: Cooke and Vowles. 1948.

Stories of over 50 years of the author's life in Nottingham. Mr. Hogarth is a Past President of the British Medical Association.

Contributions to Psycho-Analysis, 1921-1945. By M. Klein. (Pp. 416. 21s.) London: Hogarth. 1948.

Papers on psycho-analysis reprinted, with one exception, from journals.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY FEBRUARY 12 1949

N.H.S. ACT IN AUSTRALIA

The medical profession in Australia, under the guidance of the Federal Council of the B.M.A., is taking a firm stand against the scheme for a National Health Service outlined in the Enabling Act passed by the Federal Parliament at the end of last year. The Act, a full account of the debate on it in the Australian Parliament, and a leading article giving details of the negotiations between the B.M.A. in Australia and the Government are published in the *Medical Journal of Australia* for Feb. 5. A summary of the main points in the dispute appears in this week's *Supplement*. The attitude of the Government to our Australian colleagues is expressed in forcible terms in a letter from Senator N. E. McKenna, Minister for Health and Social Service, to Sir Henry Newland, President of the Federal Council of the B.M.A. in Australasia, thus.

"It [the Government] has regretfully come to the conclusion that, despite the splendid services rendered by the great number of practitioners, your Association is grievously lacking in a sense of social responsibility.

"Having exhausted every endeavour to secure the co-operation of your Association, the Government does not intend that its proposals should be further delayed or frustrated by your Council or Association.

"I have to convey to you the decision of the Government that, within the limits of constitutional power, it will proceed to put its plans into operation."

Commenting on this, the leading article in the *Medical Journal of Australia* observes that "the Government of the Commonwealth of Australia is determined to force on the people a piece of legislation which is foredoomed to failure."

Proposals for a complete medical service for Australia were considered by the Federal Council in 1940, and after these had been looked into by the Branches the proposals, modified in some respects, were adopted in 1941. The B.M.A. scheme advocated the provision for every individual of the services of a general practitioner of his own choice, and of consultant and specialist and laboratory services and of institutional treatment all to be available normally through the agency of the family doctor. It also recommended the co-ordination of the several parts of a complete medical service by the application of a planned national health policy, and the direction of the medical service to the achievement of positive health and the prevention of disease no less than to the relief of sickness.

Towards the end of 1941 the National Health and Medical Research Council put forward its views in a document entitled "Outline of a Possible Scheme for a Salaried Medical Service." The Federal Council, taking notice of this, laid down its policy in more detail in 1943, and in May, 1944, adopted the fee-for-service principle "as one acceptable substitute for any unacceptable scheme proposed by the Government." In June, 1944, the Federal Minister for Health and Social Service declared the Government's intention to introduce a service which would

be free of cost to the citizen except through "such general contribution as may be made through general revenue channels." At the same time the Treasurer, who is now Prime Minister, observed that the Government would have at its disposal after the war "a considerable number of medical graduates . . . pledged to give their services to the Commonwealth Government for a period of years." The B.M.A. in Australia interpreted the Government's intention as being one to introduce a salaried medical service and declared its opposition to this. In May, 1946, the Minister for Health informed the Federal Council that the Government's policy was to make available to every person in Australia medical attention without any direct charge for the service, and to include in the scheme "the full range of medical attention, including all modern diagnosis and specialist services." In 1947 the Federal Council drew up principles which in its view should govern a national medical service, and included in these seven of the principles drawn up by the Council of the B.M.A. in Britain. The Federal Council advocated the payment on a fee-for-service basis of practitioners and of consultants and specialists in a national medical service, and suggested that "the role of a government in hospital administration should be one of co-ordination only, leaving the control to independent boards of qualified persons." In July, 1947, the Minister for Health stated in a conference between him and the Federal Council that the Government's aim was to abolish private medical practice.

The Federal Council was prepared to negotiate with the Government provided it did not reject the following principles: (1) control to be vested in a corporate body; (2) no contract between the Government and individual practising doctors; (3) payment on a fee-for-service basis. The Federal Council proposed that, under the direction of the Minister and at a level with the Director-General of Health, there should be a controlling body predominantly medical and representative of the practising profession, the medical representatives to be the direct nominees of the profession. The Council did not admit the right of the Government to fix a fee of which it paid only a part, and demanded that a scale of benefits should be laid down. It held also that no regulations should be brought out under the Act unless first approved by the controlling body. Medical practitioners, in the view of the Federal Council, would be unwilling to undertake the necessary clerical work or incur the liabilities of acting as the agent for the patient obtaining medical benefits. The Government proposed that the patient should pay half the doctor's fee and the other half should be obtained by the doctor on application to the Government: the Federal Council objected that this would oblige the practitioner to make available to a departmental officer his clinical records and thus destroy the confidential relationship between doctor and patient. It opposes the Act (1) because control will be under the Director-General of Health and not under a corporate body; (2) because of the wide powers of the Minister in making regulations; (3) because of its objection to experimental health centres under the control of the Government; (4) because of the Government's proposals for remunerating doctors. The essential basis of the opposition of the Australian medical profession is its belief that the Government's ultimate aim is the abolition of private practice.

The *Medical Journal of Australia* points out that the Pharmaceutical Benefits Act was brought to naught by the

refusal of the profession to co-operate with the Government, and implies that the same fate awaits the National Health Service Act if the Australian Government rejects the principles which our Australian colleagues are prepared to take as the basis for a complete medical service for the people of Australia. The stage is set for an acute conflict, which will be watched with interest and sympathy by the medical profession in this country.

ENTERITIS NECROTICANS

The *Clostridia*, sporogenous anaerobes found in variety and great profusion in soil and dirt generally as well as in the lower intestinal tract of man and animals, are among the most versatile of bacteria. They play a leading part in many forms of natural decomposition, particularly that of animal carcasses. Among their purely beneficial activities two species, *Cl. pectinovorum* and *Cl. acetobutylicum*, are responsible for valuable fermentative processes, the retting of flax and other vegetable fibres and the production of acetone and butyl alcohol from maize or molasses. On the other hand they are responsible for three distinct and very different diseases in man—tetanus, gas gangrene, and botulism—and for many animal diseases. Some of the latter—blackleg, black disease, and pulpy kidney—resemble human gas gangrene in their nature though not in their apparent origin, since the traumatic factor is absent. In others—lamb dysentery, struck, and braxy—the primary lesion is in the alimentary tract, a condition which has hitherto had no recognized counterpart in human pathology.

We publish in this issue a series of papers showing that an acute and often fatal intestinal infection, due to a *Clostridium* and having close affinities with these animal diseases, can occur in man. In the first paper Professor J. Zeissler and Miss L. Rassfeld-Sternberg, of Hamburg, give an account of its occurrence in various places in Germany during the past three years. The essential lesion is an extensive necrosis of the mucosa of the small intestine, particularly in its upper part, but sometimes extending into the colon, and though nothing characteristic is discoverable in the faeces examination of the lesions themselves shows the presence of numerous Gram-positive bacilli. These have been cultivated by various observers, and the contribution of Zeissler and Rassfeld-Sternberg to this study is an examination of the characters of some of the strains isolated by themselves from eight cases of the disease, which has now been named enteritis necroticans. The organism had previously been identified as *Cl. welchii* and believed or assumed to be of type A, which is the type causing gas gangrene in man. They found several points of difference: the individual rod is somewhat larger, the colonies are rough instead of glistening, and the heat resistance of the spores is considerably greater. *Cl. welchii* is among the least heat-resistant of sporogenous bacteria: spores formed in culture do not resist boiling for more than a few minutes. Those of the new organism withstood boiling for from one to four hours, a fact which provided not only a criterion of identity but a satisfactory method of isolation. Cultures not only brought on fatal infection in

animals when injected parenterally, but when introduced into the guinea-pig's intestine caused the intestinal lesions seen in man.

The story is here taken over by Dr. C. L. Oakley, whose study of the toxins of *Cl. welchii*, begun in connexion with work on gas gangrene during the war, has since been pursued with fruitful results. It appears that only six of the eight strains behaved consistently, but the characters of these are unmistakable. They form comparatively little of the α -toxin, the main toxin of type A, causing human gas gangrene; their main product is β -toxin, and this is quantitatively neutralized by *Cl. welchii* β -antitoxin. This is the principal toxin formed by the type B organism responsible for lamb dysentery, and human enteritis necroticans must therefore be regarded as having very close affinities with this disease. On the other hand the organisms are not identical, and Oakley regards both the failure of the new strains to produce subsidiary type B toxins, recently identified by himself, and their remarkable heat resistance as entitling them to recognition as a separate type, now to be designated F.

Three further papers throw some light on this organism from other points of view. Dr. C. Dieckmann has examined 63 preserved cultures of *Cl. welchii* and found only two of type F: these were derived from the wounds of soldiers serving on the Russian front. Dr. E. Hain has found that type F is recoverable from a small proportion of miscellaneous samples of human faeces. This need occasion no surprise, especially since these strains were of low pathogenicity. Wide variations in the capacity to produce toxin account in part for the contrast between the extensive distribution of such organisms as this and the comparative rarity of the dangerous infections caused by them. (An example of the exceptional case is reported by Dr. A. L. Wyman in this issue: gas gangrene of the thigh was found to be due to an endogenous *Cl. welchii* infection spreading from a carcinoma of colon.) In another paper Dr. Hain describes a case of enteritis necroticans in which the source of infection was clearly identified as home-tinned rabbit: boiling for two hours had failed, as might be expected, to destroy the type F organism which happened to be present in this meat. Is this method of preserving food the explanation of the occurrence of this disease exclusively—so far as we know—in Germany? None of the authors discusses this matter from a general point of view. It is possible that enteritis necroticans does occur outside Germany and has hitherto passed unrecognized as a specific disease, as well it might in view of the fact that the causal organism is only by refined methods distinguishable from a normal inhabitant of the intestine. It is to be hoped that this interesting series of papers, which can fairly claim to establish the identity of a new human disease, will enable others to recognize its existence elsewhere.

It is of some interest in this connexion that Mollaret, Prévot, and Guéniot¹ have recently described a case which they claim to have identified as a human equivalent of black disease in sheep—i.e., rapidly fatal hepatic necrosis caused by *Cl. oedematiens*. Except in the fulminating character of the disease the parallel between the two conditions does not seem particularly close, and the origin of

¹ Ann. Inst. Pasteur, 1948, 75, 195.

the infection is obscure. The organism was recovered in cultures made from the liver with the fullest aseptic precautions post mortem, but it is not mentioned as having been demonstrated histologically. Despite some dubious features this case suggests that the possibility of such an infection in man may be worth while bearing in mind.

PROPHYLACTIC ARTIFICIAL LIGHTING

There is disagreement about the value of ultra-violet irradiation during the winter months as a protection against infections such as the common cold. Dr. Dora Colebrook, working for the Industrial Health Research Board, was unable to demonstrate any better health among a large number of workpeople who were irradiated than among controls who imagined they were being irradiated but in fact were not.¹ A new approach to the subject has been made by Ronge² in Sweden, who studied the effect on school-children of ultra-violet irradiation emitted from lamps which acted as the source of artificial lighting in the classrooms. A quartz mercury-vapour burner was enclosed in an outer bulb of special glass which absorbed the shorter but transmitted the longer ultra-violet wavelengths. These burners were mounted with reflectors painted with ultra-violet reflecting paint, and this paint was also used on the classroom walls. Supplementary incandescent lamps were used to tone the colour of the radiation. In Swedish schools during some of the winter months artificial lighting has to be used throughout the day, and practically no natural ultra-violet radiation reaches the earth during the winter. The dose of ultra-violet radiation in the classrooms was arranged so that some children received a daily "erythema-threshold" dose on their hands and faces, while others actually received a mild erythema dose: these latter became slightly pigmented on the exposed parts. There were no ophthalmic disturbances or other ill effects.

During this research detailed records were kept of all relevant physical and physiological observations. In Swedish children there is a seasonal variation in the plasma-calcium level, with highest values in the autumn and lowest in the late winter. This seasonal variation did not occur in the children whose classrooms were lit with the ultra-violet lamps. The haemoglobin concentration, which does not vary with the seasons, was unaffected by irradiation. A large dose of vitamin D was given to each one of a small group of children, but this did not increase the winter plasma-calcium level. Ronge devised a method of testing the physical fitness of the children by ascertaining the effect on the cardiovascular system of moderate muscular work on a bicycle ergometer. His results with this method appeared to show that the irradiated children were fitter than the non-irradiated controls. He attributed the difference to the effect of the irradiation in maintaining the amount of calcium in the plasma at summer level, but it is surprising to find that the non-irradiated children who received the large dose of vitamin D were also fitter than the controls.

Ronge also investigated the effect of the radiation on air-borne bacteria. He found that the bacterial count in irradiated classrooms was about half that in non-irradiated classrooms, and he believed that this accounted for the fact that the children in the former were less frequently absent from school than children in the latter. As the intensity of irradiation decreased when the emitters grew old, the children's absences became more frequent. No

claim is made for any "protective" effect other than that ascribed to the bactericidal action of the ultra-violet radiation.

This experiment differs from others in that the irradiation was more or less continuous while the children were at school, and its main purpose was to determine what effect if any this irradiation had on the physical fitness of the children. A possible flaw in the experiment lies in the difficulty of controlling the mental attitude of children undergoing performance tests. Schoolboys would quickly realize that some were being taught in classrooms lit by the new ray while others were not, and it seems likely that the irradiated boys would perhaps regard themselves as "supermen," while the non-irradiated might not have the same confidence in their ability to put up a good performance.

PROTECTING THE SKIN FROM IRRITANTS

The prevention of industrial dermatitis depends to a large extent upon cleanliness. When the cause of dermatitis is due to an allergic sensitiveness to some external contact the most scrupulous cleanliness and elaborate protective measures may fail, but where the occurrence of dermatitis depends upon the length of the period during which the irritant is in contact with the skin such measures are of major importance. The first requirement is a clean machine and a clean factory, to ensure that as little of the potential irritant comes into contact with the worker as possible: this is a problem for the engineer and not the medical man. Then follows the need to protect the worker by suitable garments and by the avoidance of prolonged contact with garments which may become impregnated with the irritant. Some help may be obtained from the use of appropriate barrier creams on exposed parts of the skin, but this procedure must be carefully and continuously supervised by a doctor or experienced nurse, and even so it has its limitations. The most important prophylactic measure is simple but efficient washing with soap and water immediately after work. The more knowledgeable workman has long known that washing is more effective when soap is massaged into moist hands to produce a thick soap emulsion than when it is diluted with large quantities of water, and in a recent paper on the subject of skin cleansers and protective creams Cruickshank¹ confirmed this and has suggested that even better results are obtained by using equal parts of milled, dried soap powder and fine wood flour. This no doubt has adsorptive properties and perhaps some abrasive action, and it prevents caking of the soap powder. The mixture would not be suitable for putting up in tablet form because of a tendency to abrade the skin.

In assessing the value of cleansers and barrier creams as a protection against the irritation caused by mineral oils Cruickshank carried out tests on three grades of oil—machine oil, cutting oil, and soluble oil—which vary in the ease with which they are removed from the skin. The efficacy of cleansing procedures was judged by observing the amount of fluorescence under ultra-violet light from oils remaining in the follicles. He did not find that barrier creams gave satisfactory protection, though creams with a soapy base were effective for limited periods; they also have the virtue of diluting the irritant and of making easier its removal by washing. Thorough cleansing of the skin after work is still of the first importance, and the sulphonated oils, which have found favour as cleansers in industry, proved less effective in removing the oil than the soap powder and wood flour emulsion.

STREPTOMYCIN IN THE TREATMENT OF TUBERCULOSIS

REPORT OF A SUBCOMMITTEE

The Standing Advisory Committee on Tuberculosis in August last year set up a subcommittee* to advise the Ministry of Health and the Department of Health for Scotland on the application of streptomycin. The subcommittee has now prepared a report in which the following points are stressed.

Miliary and Meningeal Tuberculosis

For miliary and meningeal tuberculosis a daily intramuscular dose of 20 mg. per pound body weight up to a maximum of 2 g. is recommended. Intramuscular treatment should be maintained for at least four months, and in some cases further courses may be required. In addition, for meningitis 50-100 mg. of streptomycin dissolved in 5-10 ml. of saline should be injected intrathecally daily. The optimal frequency of intrathecal injection is not yet established, but it seems advisable in the average case to give intrathecal injections daily for the first three weeks and then every other day for two weeks. Further courses of intrathecal injection are probably necessary. The course of tuberculous meningitis under streptomycin treatment is very variable, and may be complicated by spinal block interfering with intrathecal therapy. Among the many schemes of dosage that have been used the following are two examples:

(i) Intramuscular streptomycin during weeks 1-3, 5-7, 10-12, 14-16. Intrathecal treatment every day during the first week, and on alternate days during weeks 2, 3, 5, and 10.

(ii) Intramuscular streptomycin during weeks 1-12, 17-20. Intrathecal streptomycin daily during weeks 1-4, 9-12.

In tuberculous conditions other than miliary and meningeal, 2 g. daily was at first the usual dose for all adult patients, but this produced toxic effects in most cases; 1 g. a day has been found to be less toxic, and is possibly equally effective; 0.5 g. a day is still less toxic, but its efficacy has not yet been fully established. It may be more satisfactory to adjust the dosage to body weight. As a general guide to dosage in both children and adults, 10 mg. per pound body weight per day is suggested. Since toxic effects are more severe in older age groups, the dosage should be lower for patients over the age of 45. The most recent evidence suggests that the maintenance of a fairly constant streptomycin blood level by injection at frequent intervals during the day is unnecessary. The administration of the daily dose in one or two injections is recommended.

No single scheme can be considered suitable for all forms of tuberculosis. According to present knowledge maximal effect is reached within the first one or two months, and for most cases other than miliary or meningeal tuberculosis it is useless and may be dangerous to treat continuously for more than three months. On the other hand, it is probable that treatment for less than one month is ineffective.

Toxicity

Vestibular damage is the commonest toxic effect. The damage to vestibular function is often irreversible, but some degree of compensation occurs, and unless the signs of dysfunction are sought the sequelae may be overlooked, particularly in the later stages. The danger of toxic effects increases with age, and they occur with especial frequency after middle age.

Vertigo most often begins in the fourth or fifth week of treatment. Nystagmus or altered vestibular reactions are frequent and may occur even in the absence of subjective symptoms. Difficulty in reading is sometimes complained of during the early stages of vertigo, but is usually transitory.

Careful watch should be kept for evidence of vestibular dysfunction. Tests such as the caloric reaction should be carried out where feasible, and in ambulant patients functional tests such as the Romberg test, walking along a straight line with eyes open and closed, or walking on a mattress.

*Sir Robert Young is chairman of the Streptomycin Subcommittee, and the members are: A. S. Hall, D. P. Sutherland, C. Price Thomas, Norman F. Smith, J. G. Scadding, E. H. Hudson, G. S. Todd, Andrew Morland, N. Lloyd Rusby, L. E. Houghton, W. E. Snell, A. L. d'Abreu, James Watt, P. M. D'Arcy Hart, Marc Daniels, and J. H. Harley Williams, who is the secretary.

Nausea, anorexia, and vomiting may begin during the third or fourth week and may be quite severe, but are often relieved by antihistamine drugs such as "benadryl" 50 mg. by mouth. Sensitization reactions such as skin eruptions and pruritus in the early stages of treatment are also usually relieved by antihistamine drugs.

Local pain at the site of injection may be relieved by adding 0.5 ml. of 1% procaine to the solution for injection.

Albumin and casts have been found in the urine in some cases. With the moderate dosage at present used, these abnormalities subside without discontinuing treatment. Serious neurological sequelae due to meningitis should be distinguished from toxic effects due to streptomycin.

In view of the risk of sensitization in attendants handling streptomycin it is advisable that they should wear rubber gloves while handling streptomycin and should wash the hands after removing the gloves.

Streptomycin Resistance

This eventuality must be borne in mind. A long-term plan of treatment should be made; in this a course of streptomycin can only be a part, and one which can probably not be repeated effectively. If the drug is indiscriminately used particularly in advanced cases with copious sputum, resistant strains will be disseminated. In order to detect dissemination of resistant strains, at the start of treatment in any particular case material if available should be collected for culture and the bacilli isolated and tested for streptomycin sensitivity.

In the present state of knowledge the simplest general criterion recommended for selection for streptomycin might be as follows: "Pulmonary tuberculosis in which the lesions requiring treatment are of recent development, progressive, and unlikely to benefit from conventional methods (e.g., bed-rest and/or collapse therapy) alone." Streptomycin should not be used as the only therapeutic measure in pulmonary tuberculosis. Indeed its major role may be to make possible the use of collapse procedures which in its absence would have had to be delayed or never performed.

Indications

Every diagnosed case of miliary and meningeal tuberculosis should be treated, but treatment of meningitis is difficult and prolonged, and miliary cases may be complicated by meningitis even while under streptomycin treatment. For these reasons streptomycin should be given only in hospitals with the facilities.

Streptomycin is of proved value in ulcerative tuberculosis of larynx, trachea, bronchi, tongue, and pharynx. In laryngitis and tracheo-bronchitis the diagnosis should be confirmed when possible by laryngoscopy or bronchoscopy before treatment started, and the examination should be repeated during and at the end of treatment in order to provide full assessment of the effects of streptomycin therapy. No additional advantage is apparently derived from giving streptomycin by method other than intramuscular.

Prophylactic use of streptomycin to "cover" routine thoracoplasties in the hope of decreasing the incidence of post-operative spreads is not recommended on present knowledge. It should be reserved for the treatment of spreads when they actually occur. Prophylactic use before and after resections of the lung for pulmonary tuberculosis is probably of value, but the best scheme of dosage for this purpose is not yet established. The value of streptomycin injected locally into infected subscapular spaces after thoracoplasty is established. Systemic treatment in addition to local may be of value.

Streptomycin often produces healing in tuberculous cutaneous sinuses and fistulae; local treatment in addition to systemic may be of value.

Favourable results have been reported in tuberculosis of the alimentary tract and peritoneum. Symptomatic improvement may occur rapidly, but relapses are frequent. Streptomycin may prove of benefit in some types of genito-urinary tuberculosis, and a few encouraging results have been obtained in bone and joint tuberculosis, but these are far from conclusive, and streptomycin treatment here too cannot replace standard therapy.

All the recommendations here summarized are provisional and will require modification as further experience accumulates. It is certain that indiscriminate use of streptomycin carries with

dangers both to the individual and to the community. The tendency to "try" this drug in every form of tuberculosis is to be condemned.

Streptomycin is generally supplied in one of three forms—as the hydrochloride, the sulphate, or a calcium chloride double salt. Since a mixture of the sulphate and the calcium chloride complex in the test-tube produces a precipitate of calcium sulphate it is recommended that a change-over from one of these two salts to another in intrathecal administration (and probably also in intramuscular administration) should be avoided; if a change has to be made it is recommended that several weeks elapse between the last injection of the one salt and the first injection of the other.

ROYAL MEDICAL FOUNDATION OF EPSOM COLLEGE

PENSIONS, SCHOLARSHIPS, GRANTS

Epsom College has available at the moment one or two t. Anne's Scholarships for girls attending Church of England schools. Candidates must be fully 9 years of age and the orphan daughters of medical men who have been in independent practice in England or Wales for not less than five years. The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school selected.

There are also available: (a) pensions for necessitous medical men fully 55 years of age, provided they have been registered for five years, and for the widows of medical practitioners who are 60 years and upwards (awards are made as vacancies occur); (b) scholarships and grants for children of either sex, not necessarily orphans, but candidates must be of public-school age and in need of such help; (c) grants from the Eastes Trust for the relief of registered members of the profession of any age, their widows and orphans, and for the educational assistance of their daughters or sons. Full information and forms of application are available, on request, from the secretary, Epsom College, Surrey.

Reports of Societies

RENAL LESIONS ASSOCIATED WITH PREGNANCY

A meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine was held on Jan. 21, with Professor HILDA LLOYD in the chair, for a discussion on the pathological features of cortical necrosis of the kidney and allied conditions associated with pregnancy.

Professor JAMES YOUNG said that the discussion concerned those acute states in relation to pregnancy which had as their dominant features anuria or severe oliguria, increasing azotaemia, and uraemia. The result was death, usually within eight to twelve days, or, alternatively, increasing diuresis associated typically with a rapid disappearance of the uraemia, ending in the ordinary case apparently in complete recovery. This clinical sequence was found in cases of accidental haemorrhage, anuria being more frequent in "concealed" than in so-called "revealed" cases, and in obstructed labour, especially where there had been long-continued compression trauma of the soft passages. In concealed haemorrhage and in puerperal trauma the sequence was usually preceded by clinical shock, which might be severe. A striking feature in both these conditions was the selective nature of the renal lesion. In the case of traumatic anuria, however, the renal failure might be associated with a "massive" degenerative lesion of the liver and jaundice, the degeneration affecting especially the mid-zonal and central regions of the lobule. While the renal lesion might be typical, the fatigue of prolonged labour, severe nutritional disturbances, and inept anaesthesia had often contributed to the production of complex pathological changes.

The same sequence was also found in rare cases of eclampsia; very rarely in the course of a pregnancy which seemed otherwise normal; and in a group of conditions in which it was merely incidental to the pregnancy, as, for example, incompatible transfusion, or after the administration of sulpha drugs, or in association with certain infective conditions in the puerperium, especially that due to *Cl. welchii*.

Aetiology

Of the proximate aetiology little was known. It had been suggested that the renal lesion was due to anoxia from circulatory collapse following the shock of utero-placental haemorrhage. But in 59 consecutive cases of severe haemorrhage at childbirth necessitating blood transfusion the anuric sequence occurred only in 5 out of 10 cases of concealed accidental haemorrhage, and in none of the 37 cases of post-partum bleeding and the 12 cases of placenta praevia. Moreover, all degrees of the anuric phenomenon were clinically recognizable, and in the milder cases there had often been no evidence of shock whatever. Even complete suppression of urine could occur in a case without any shock.

The view sometimes taken that the whole sequence—accidental haemorrhage, anuria, azotaemia—was merely one manifestation of pregnancy toxemia was supported by the frequency with which it occurred as the final and critical climax in a toxemic patient; but there was no doubt that the anuric and uraemic sequence post-dated the acute utero-placental lesion. He thought the conclusion was not to be evaded that it was this lesion which precipitated the damage to the kidneys.

Confining himself to the findings in cases of concealed accidental haemorrhage, Professor Young said that, despite the uniformity of the clinical sequence and of the utero-placental changes in such cases, two quite different types of lesion were found in the kidney: (1) bilateral cortical necrosis, which was now believed to be the rarer of the two, and (2) the lower nephron lesion, affecting the second convoluted and collecting tubules, associated with degeneration of the epithelium and, though not invariably, with the deposition of crystals of blood pigment in the tubules.

The resemblance between the renal lesions in these and in crush cases raised the possibility of a basic similarity in genesis. It seemed unlikely that tubal blockage by pigment casts was an essential factor in either condition. Since in both conditions there was massive tissue damage—damage of muscle in the anuria following crush injuries and of the placenta in concealed accidental haemorrhage—it was conceivable that toxic metabolites from the tissues played an essential part. In the anuria of the crush syndrome recovery could be expected in a considerable proportion of cases with appropriate treatment. The majority of cases of anuria following accidental haemorrhage recovered, and it might be assumed that the lesion in these obstetrical cases was more likely to be of the lower nephron type and less likely to be cortical.

Finally, Professor Young reminded the Section that the pathology in these cases might have a special relevance to the genesis of pregnancy toxemia. He had referred already to the by no means uncommon occurrence of eclampsia with or without the anuric sequence in cases of concealed accidental haemorrhage. Further, it had long been known that blood pigment casts were relatively common, with or without tubular degeneration, in eclampsia. The significance of such findings was not easy to assess. It was clear that they did not constitute more than an occasional occurrence, and even in the kidneys of a patient with eclampsia dying from this type of anuria the pigment casts might be absent.

Other Views

The remainder of the discussion took the form of short reports by a number of workers. Dr. G. M. BULL (with whom were associated Dr. A. M. Jockes and Dr. K. Lowe), speaking of some work at Hammersmith Hospital, said that they had been interested in cases of anuric uraemia presenting some special problems. The most important point in treatment in the anuric phase was the maintenance of a correct water balance. Water overload was the most frequent cause of death in anuria. He emphasized the importance of a salt-free and potassium-free diet. Cortical necrosis was almost invariably fatal; in the other type of lesion recovery took place in a large proportion of cases.

Dr. J. F. SMITH described the morbid anatomy of uraemic cortical necrosis. It was not only in cases of septic abortion that these conditions were found; he had examined material from 17 fatal cases of eclampsia and had found pigment casts in 3, with some lower nephron changes in each case. He added that he had come across some cases of severe oliguria associated

with pregnancy in which death occurred suddenly after the administration of potassium citrate in substantial doses. If such a drug was given it was desirable that it should be the sodium rather than the potassium salt.

Professor KENNETH FRANKLIN discussed experimental findings and showed a coloured film illustrating the renal "shunt" mechanism in rabbits. He and his colleagues had advanced the hypothesis that in the toxæmia of pregnancy there was an increasing tendency to renal shunt. He defended the use of the word "shunt," although it had been challenged; it was a word coined and widely used in America, and its dictionary definition was "movement from one set of rails to another," which was what happened. When the tendency to shunt was slow it might be regarded as a physiological reaction calculated to give the uterus and its contents a better blood supply at the expense of the renal cortex.

Dr. J. F. HEGGIE described the first demonstrable lesion in the kidney in cortical necrosis, and showed the findings in an early case in which the patient died after two days' anuria. The glomeruli were shown uniformly dilated and filled with red blood corpuscles. At the same time or shortly afterwards congestion of the glomeruli occurred. The pressure might be such as to force red blood corpuscles from the main stream into the wall of the interlobular artery. He also spoke of the conditions in which recovery was possible. Dr. S. J. DE NEVASQUEZ believed that the essential primary lesion was a diffuse necrosis and discussed the factors which led to blockage by stagnation of blood cells.

Mr. T. L. T. LEWIS grouped the cases as (1) fatal cases of anuria in which the diagnosis of cortical necrosis was made post mortem; (2) fatal cases in which the diagnosis of lower nephron necrosis was made; and (3) recovered cases, in a few of which a biopsy had been carried out. In the first two groups the appearances were distinctly different, but the clinical pictures were similar. The withdrawal of heavily blood-stained urine heralded the onset of cortical necrosis. The patient remained cheerful all the time until near the end, when she became comatose. All the evidence pointed to a circulating toxin, and it was conceivable that following the sudden appearance of a toxic substance in the circulation the kidney dealt with it in one of two ways: either the remote vascular mechanism was brought into effect or else the specially susceptible cortex became engorged and finally blocked. In the first case lower nephron necrosis and, in the second, cortical necrosis developed. The latter was invariably fatal; lower nephron cases recovered, given time, and time was the vital element in recovery.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY

Following the annual general meeting of the society at the University of Manchester on Jan. 21, the new president, Mr. S. B. HERD, of Liverpool, took the chair.

Mr. S. W. LIGGETT described a case of spontaneous rupture of the uterus in a patient aged 76 who had been operated on for prolapse at the age of 60. Sixteen years later she developed symptoms of torsion of an ovarian cyst and at laparotomy was found to have free blood in the peritoneal cavity, a distended uterus and left tube, and perforation of a fibrous sacculus in the left uterine cornu. Subtotal hysterectomy with left salpingo-oophorectomy was carried out successfully.

Dr. W. CALVERT read a paper on ectopia vesicae. He had been able to trace twenty women who between them had had twenty-eight children, and after reviewing these cases he described one case which had been brought to his notice. This patient had had the ureters transplanted into the colon and the bladder excised for ectopia vesicae as a child, after which she had been able to live an active ordinary life as a schoolgirl and secretary. After marriage she had a successful vaginal plastic operation for dyspareunia and later conceived. During pregnancy there was renal insufficiency and near-term caesarean section with sterilization was performed, a healthy child being delivered. Recovery was uneventful.

Mr. F. J. MILWARD described cases of endometrioma of the umbilicus in a patient aged 38, and persistent vitelline duct with subadjacent cyst and Meckel's diverticulum in a child of 9 years.

Correspondence

Aetiology of Erythema Nodosum

SIR,—In your annotation on this subject (Jan. 29, p. 188) you state:

"In the majority of adults . . . migratory arthritis was part of the clinical picture, and in some adults similar attacks of polyarthritis without erythema nodosum had occurred up to twenty years before. The belief that erythema nodosum is a manifestation of acute rheumatism dies hard in this country, yet despite the frequency of fleeting joint and limb pains Favours and Sosman could find no evidence that there is any close relationship between the two diseases. In fact they conclude quite categorically that erythema nodosum is not a form of rheumatic fever."

Sir Arnold Stott and I published a short paper¹ in 1940, in which we described a series of such cases sent to an Arm hospital, mostly with the diagnosis of rheumatic fever and presenting in many instances also the appearance of erythema nodosum. We were able to show as the result of serial blood cultures that these cases were in fact instances of low-grade meningococcal septicaemia. The history of recurrent attack in several of these cases also went back for a number of years. Subsequently other cases were seen and recognized as being of the same aetiology. We concluded that the condition although unrecognized in most cases for what it is, may not be uncommon.—I am, etc.,

London, W.1.

Overdose of Surface Analgesics

SIR,—I should be interested to know why Dr. D. Wilson (Jan. 29, p. 197) found it necessary to use such a great concentration as 10% cocaine hydrochloride for anaesthetization of the urethra. I have found a mixture of equal parts of 1% cocaine hydrochloride and 1% sodium bicarbonate preparation immediately before use quite satisfactory, and it seems likely to be safer than 10% cocaine hydrochloride. The addition of an alkali to cocaine to enhance its action is discussed in Martindale's *Extra Pharmacopoeia* under the heading "Activated Alkaloidal Solutions" (vol. 18), and under the heading "Injectio Cocainae et Sodii Bicarbonatis" (vol. 21) is shown the same mixture with "chloroform," a mixture favoured by the late Mr. Canny Ryall.

Incidentally, I should like to add a tip for urethroscopists who like to anaesthetize the urethra before examination. The urethra is filled with the anaesthetic solution and the patient does not urinate after it has had time to take effect the urethra is inconveniently wet, requiring much mopping, but if he urinates before the instrument is passed very little mopping is required. I must not occupy your space by discussing the reason.—I am, etc.,

London, S.W.1.

L. W. HARRISON.

Anuria

SIR,—Dr. J. F. Heggie's argument (Jan. 22, p. 151) appears well for comment. He states that owing to certain events vasoconstriction of the renal arterioles "brings about the greatest reduction in calibre" of those supplying glomeruli "in the outer- and mid-cortical" regions, while "as a consequence the circulation through the juxtamedullary (15%) and some (5%) deep cortical glomeruli and the medulla is greatly augmented." May I ask him how it comes about that a general stimulus causing vasoconstriction of renal arterioles should be specific, affecting the arterioles of the outer two-thirds of the cortex and so unaffected those of the inner third that augmented blood flow through occurs? What is sauce for the goose is sauce for the gander! Dr. Heggie's argument appears untenable.

On Jan. 21, 1949, at the Royal Society of Medicine, eight papers on the pathogenesis of cortical necrosis of the kidney were read. Not one of the speakers mentioned a fundamental condition affecting the renal blood flow—the secretion of urine.

on October, 1947, at a discussion on the renal circulation I pointed out¹ that Brodie had shown that if the ureter be clamped during diuresis the kidney becomes almost bloodless.² That during activity of an organ the blood flow through tends to be checked, to be limited, or even stopped is not peculiar to the kidney. Each time the heart contracts, the capillaries in its musculature, permeating the tissues of the ventricles, are clamped, so that no blood goes through at all.—I am, etc.,

Rusby.

Infected Disk after Lumbar Puncture

SIR,—In their article on infected intervertebral disk after lumbar puncture (Jan. 22, p. 132) Mr. L. L. Bromley, Dr. Donaldson Craig, and Mr. A. W. Lipmann Kessel do not mention the simplest and most effective precaution against damage. For very many years it has been the standard practice among anaesthetists to tilt the needle towards the patient's head when doing lumbar puncture. If pushed too far the point will impinge on the next higher vertebral body, which may damage the former but not the latter. If, however, the needle is introduced at right angles to the skin over-enthusiasm will force its point into the intervertebral disk. In young patients with flexed spines the disks bulge towards the dura, and puncture of the thin annulus fibrosus may cause seepage of the nucleus pulposus with ultimate collapse of the disk. The unfortunate patient is then all set for a long period of invalidism.—I am, etc.,

St Albans, Herts

C. LANGTON HEWER.

Cinchocaine

SIR,—I beg to comment on the new official name of that familiar anaesthetic drug "nupercaine." It is now to be called cinchocaine. This name can be justified pharmacologically in that it suggests, rightly, a derivative of cinchoninic acid, but I feel that it is dangerous. Imagine a verbal order given by an impatient or irate anaesthetist (or conceivably a surgeon) in the course of a busy list. How easily the last two syllables might become the operative ones. It is true we put our cocaine in distinctive bottles, and in our hospital we colour the solution, but no precautions can be too great. I suggest that quinoacaine would be a safer name and yet have the same pharmacological justification.—I am, etc.,

Birmingham.

L. T. CLARKE.

Spinal Anaesthesia for Caesarean Section

SIR,—It is interesting that in the same issue of the *Journal* Jan. 22 there should be a letter on the evergreen controversy which rages around this subject (p. 153), a report of a calamitous long-term sequel of lumbar puncture (p. 132), and another letter on the question of classical v. lower-segment operation (p. 156). It is unfortunate that so many of the disasters following lumbar puncture take so long to mature, because the original operator may be unaware that they have taken place or that his puncture has been anything less than 100% successful. It is also probable that minor disabilities such as backache may result from trauma inflicted at lumbar puncture and never come to light at all, being accepted by the patient as just another load to be borne in these hard times.

Lumbar puncture is often a very difficult operation to perform without touching bone or intervertebral disk, and is certainly not made easier by the presence of a full-term uterus, and I feel that a procedure with so many distant dangers is not justifiable for caesarean section except when the baby is very premature. Babies delivered by caesarean section generally cry immediately, whatever the anaesthetic, if it is chosen and given with reasonable skill. Ether in concentration enough to give plane 1 anaesthesia has remarkably little effect on the baby—far less than that of $\frac{1}{4}$ gr. (16 mg.) of morphine given two hours before.

But the babies which fail to cry are usually shocked, not anaesthetized. If the shock is not due to sub-oxygenation, which it need never be, it is in my opinion due mainly to trauma, and I think that the baby delivered through a poorly

developed lower segment, after a prolonged tussle with Willert's and other forceps, is likely to be feeble for precisely the same reason as if it had been delivered after a difficult high forceps, and the anaesthetic has very little to do with it.

Mr. Percy Malpas (p. 156) tells of a case where extraction was impossible through the lower segment. There are many cases where it is wellnigh so, and in these, where a general anaesthetic has been given and the baby has to be resuscitated, the anaesthetist comes in for more than his fair share of the blame, while babies delivered easily and rapidly by a classical operation hardly ever give anyone a moment's anxiety.

I agree with Mr. Duncan Ballantine and Dr. F. L. Robertshaw (p. 153) that it is desirable to maintain controlled respiration or 100% oxygen inhalation while the uterus is emptied, but surely the first is rather a horrible experience for a conscious patient under spinal anaesthesia; while if she has to be given a whiff during this critical stage, is not the whole object of the spinal defeated?—I am, etc.,

Colchester, Essex.

J. N. FELL.

SIR,—I have followed the recent correspondence on spinal analgesia for caesarean section with considerable interest and some amusement. I entirely agree with Dr. N. Beattie (Jan. 15, p. 114) that most of the hazards which are theoretically put forward against spinal analgesia have not been encountered in practice by those who have had personal experience of this procedure.

Some time ago I wrote to the *Journal* relating my impressions on watching Mr. Rufus Thomas performing lower-segment caesarean section under spinal analgesia. As I said at that time, I was most impressed with his technique and with the results, and I also stressed that I was at that time the only gynaecologist who had taken the trouble to see Mr. Thomas at work, although he had been advocating spinal analgesia for nearly ten years before I visited his clinic. Since then I have personally performed considerably more than one hundred lower-segment caesarean sections under "heavy" spinal analgesia, and I have had no reason to change my opinion as to the excellence of the method.

The uterus contracts usually extremely well after the baby has been removed, and bleeding is minimal. The baby causes no anxiety whatsoever, and frequently cries the moment that its head is delivered and when its body is still in the uterus. Falls of blood pressure do occur occasionally, but are not serious providing the technique described by Mr. Thomas is carried out, and the post-operative recovery has been in my experience uniformly excellent. It allows lower-segment caesarean section to be performed quietly and efficiently, and although I have on several occasions employed local anaesthesia I have not been able to obtain such satisfactory results so far as the actual operation is concerned.

I notice that Dr. Beattie refers to the use of light "nupercaine" anaesthesia and Mr. Duncan Ballantine and Dr. F. L. Robertshaw (Jan. 22, p. 153) to the use of an isobaric solution. About these two methods I cannot personally give any opinion, but I am in entire agreement with Mr. Rufus Thomas that nobody condemns all forms of inhalation anaesthesia simply because chloroform may at times be dangerous. Similarly, it is illogical to condemn all forms of spinal analgesia.

Mr. Rufus Thomas has obtained his excellent results, now amounting to nearly four hundred and fifty caesarean sections without a maternal death, using heavy nupercaine, and my results have been obtained using in the vast majority of cases heavy nupercaine and in other cases some form of "heavy" solution. None of my babies have been stillborn, and I have had no maternal deaths.

—I am, etc.,

London, W 1

D. G. WILSON CLYNE.

Malignant Tumour of the Small Intestine

SIR,—This communication on a case of primary jejunal cancer is prompted by Mr. F. J. C. Matthews's report (Jan. 22, p. 138, of the same type of growth in the ileum.

My patient, a man aged 53, was admitted as a case of perforated duodenal ulcer during Bristol's worst period of blighting in October, 1940. He gave a three years' history suggestive of ulcer and had been in hospital under Dr. Richard Clarke, then senior physician. Skiagraphy had shown a pre-pyloric ulcer, but in the test meal the maximum rise of HCl was 9 (N/10 NaOH).

On examination he was somewhat flushed, fatty, and inclined to sweat. The only abdominal finding was epigastric tenderness.

Per rectum there was nil amiss. Pending operation he remained very miserable.

At operation (Oct. 11, 1940) I was astonished to find a typical string carcinoma on the jejunum, 10 in. (25 cm.) from the duodeno-jejunal flexure. In the related mesentery was a cluster of glands more or less discrete but suspiciously enlarged. To embrace these in the excision a large wedge of mesentery was excised, based on a 12-in. (30-cm.) resection of jejunum. Biopsy by Dr. A. D. Fraser revealed "columnar-celled adenocarcinoma of jejunum. Mesenteric glands all show subacute inflammatory changes." Two months later he was a "changed man."

On Feb. 12, 1946, when next I saw him, he reported that he had been taking alkaline stomach powders during the previous four months. Dyspepsia persisted, and skiagraphy (September, 1948) disclosed a peptic ulcer of finger-tip size in the lower curve of the stomach. He was transferred to the care of my general surgical colleague, Mr. Melville Capper, who agreed there was no sign of abdominal cancer. Under medical treatment his symptoms abated, and by December, 1948, the ulcer crater was obviously smaller.

The case is reported as an example of jejunal carcinoma apparently free from recurrence eight years after excision.—I am, etc.,

Bristol.

A. WILFRID ADAMS.

Arsenical Toxicity

SIR,—Having read your annotation "Arsenical Toxicity" (Jan. 1, p. 25) quoting the work of Sexton and Gowdey¹ on the value of vitamin B₁ in arsenical encephalopathy, I would like to draw your attention to an article by me in the *British Journal of Venereal Diseases*² on five cases of this complication which occurred during intensive "mapharside" therapy.

It will be seen that I pointed out the clinical and pathological similarity between arsenical encephalopathy and syndromes resulting from deficiency of vitamin B₁ (i.e., alcoholism, Wernicke's encephalopathy, etc.), and that the use of vitamin B₁ appeared to be of distinct value both in prophylaxis and treatment. Furthermore, I suggested that pyruvic acid estimations might be an added safeguard in patients undergoing intensive arsenic therapy and that in view of the known role of the other members of the vitamin B complex in intracellular metabolism better results may be obtained by using the whole complex rather than vitamin B₁ alone.

Two further points in the annotation call for comment. (1) It is stated that brain haemorrhages occur in fatal cases, but it is well known that on several occasions these have been absent and only cerebral oedema found post mortem. I therefore suggested that the primary pathological change in arsenical encephalopathy is intracellular oedema, which only at a later stage gives rise to haemorrhage and focal necrosis. This conception of the basic pathological change is important not only in emphasizing the difficulties of early diagnosis but also in understanding that the changes are completely reversible.

(2) *Hyperglycaemia*. Blood-sugar estimations were carried out in several patients in our series and no significant change in blood values was found. I find it difficult to understand why hyperglycaemia should occur, since the metabolism of glucose is interfered with at the pyruvic acid level and not initially.

Finally, more mature consideration of all the factors involved in arsenical toxicity as a whole has led me to believe that the liver plays some as yet unknown but vital part in the interaction of arsenic, vitamin B, and intracellular metabolism.—I am, etc.,

London, W.1.

Taking Children's Temperatures

SIR,—We read with great interest the article on rectal temperature-taking by Professor Alan Moncrieff and Dr. B. J. Hussey (Dec. 4, 1948, p. 972) and feel that to many practitioners it will come as a valuable confirmation and contribution in the field of clinical paediatrics.

In our hospital, where most of the patients are Zulus, temperatures are taken rectally in doubtful cases in children up to 5 years of age. Dr. Joan Malleson's timely warning (Dec. 18, p. 1078) comes opportunely, however, more especially

as we have recently had misgivings as to the effects of stimulation of this kind in infants—misgivings reinforced by closer knowledge of the almost universal custom found in Zululand of the daily or even thrice-daily administration of enemas to infants. These enemas may be either medicated or plain, and are given with a hollow reed or stem inserted into the child's anus. The mother is convinced that were this not regularly done the child would not have its bowels opened.

Various effects follow upon this custom: in the simple cases the mother brings the child with "sores in the rectum" and, everting the anal skin, shows the pink mucosa which to her is the "sore." In the great majority of cases the child shows marked disapproval of this examination, wriggling and crying lustily. We are not yet satisfied as to the more complex effects of such hyperstimulation, but tentatively suggest that it may cause serious emotional imbalance, particularly in the sexual sphere. The gross hysterics found in a very high proportion of adolescent Zulu girls, constipation, vaginismus, etc., may quite possibly have their early origin in severe anal stimulation in infancy.

It is of interest to note that the Zulus themselves seem to have realized some connexion between anal stimulation and sexuality. In *The Social System of the Zulus* Krige writes (p. 67):

"Every child is supposed to be tainted at birth with a constitutional defect called isigwemba, which is held to be the cause of several ailments such as unusual sexual irritability, causing lecherous inclinations in adults or disposition to eczema, etc. To get rid of this taint the stem of a castor oil or umsenge leaf (*Cussonia spicata*) or a stalk of fibre is thrust by the mother into the rectum of the child and vigorously twirled round between both hands until, by scraping on the membrane of the bowel, blood is copiously drawn. Not infrequently children die from this treatment."

While rectal temperature-taking by the sophisticated physician can hardly be fairly compared with the barbaric practices of the Zulu, we might do well to exercise humility in our judgment when we number among our own scientific advances the development of the atomic bomb.

In view of the possible danger of rectal stimulation, however innocently intended or skilfully accomplished, it might be wise to enter into no fixed routines of rectal temperature-taking, but rather to exercise clinical judgment in each case. A temperature difference between 103° F. (39.4° C.) and 103.5° F. (39.7° C.) would not appear in a case of lobar pneumonia to be of great import in assessing the total pattern of signs, while even in a case of rheumatic fever, where slight deviations from normal are important, we have equally valuable guides in the pulse rate and erythrocyte sedimentation rate.

We have banished the soap stick from the nursery. Should we abolish routine rectal temperature-taking, keeping it only for cases where slight differences are vital?—We are, etc.,

S. G. LEE.

E. A. BARKER.

Nqutu, Zululand.

SIR,—Referring to the recent correspondence in the *Journal* on the taking of rectal temperatures, it seems remarkable to me that there has been no letter from psychiatrists supporting the position taken up by Dr. Joan Malleson (Dec. 18, 1948, p. 1078), who calls attention to the psychological dangers that may ensue from interference with the anal parts of infants. She quotes the late Dr. Forsyth's teaching in support of this—namely, "that all interference with the bodily orifices should whenever possible be avoided; for, being erogenous zones they will quickly become 'conditioned' either positively or negatively to interference, and may later become responsible for various functional disturbances."

As a matter of interest, some six years ago in the *Journal* of Oct. 31, 1942 (p. 528), I published a letter attempting to put forward much the same views as Dr. Forsyth. In that letter I protested against Professor McNeil's recommendation that constipation of infants should be treated by frequent insertion of the doctor's little finger in the baby's anal canal. I gave an account of the psychological disorders of emotion, character and sexual developments that can ensue from this practice and similar methods of interference.—I am, etc.,

London, W.1.

A. CYRIL WILSON.

Approach to the Frontal Lobe

SIR,—Dr. P. Glees's plea (Jan. 29, p. 193) for co-operation between neurosurgeon and psychiatrist could not be better illustrated than in the problem of prefrontal activity. It is fairly certain that leucotomy by the standard or orbital approach, or by any other approach, is not the final answer to the surgical treatment of mental diseases.

In all neurophysiological research the task of solving a particular problem often draws the attention and interest of many investigators, and the literature of to-day is full of their now discarded claims. A new approach is useful for giving a different line of thought, and its recognized weaknesses and dangers can only give stimulation for further research. The work of Freeman has followed on "older methods" of bilateral section and may possibly lead to further observations and experiments which will ultimately cause rejection or modification of the original. I consider that prefrontal activity can be controlled by regulation of local blood supply and that this procedure in the hands of the neurosurgeon may become the operation of choice.

Whatever method is adopted or is subsequently fashionable, the selection of patients is best left to the psychiatrist, who will have the advantage of observing them for many years afterwards. Too often the experience of the neurosurgeon is limited to the post-operative sequelae. His interest in the patients ceases with their discharge from the ward. Neither is the psychiatrist fully equipped for their accurate study, as he has no knowledge of the exact pathways that have been severed in each case. Only when we have a precise method of interrupting clearly defined pathways will he be able to give a clear interpretation of its value.—I am, etc.,

Leeds.

P. P. NEWMAN.

SIR,—The letter from Dr. P. Glees (Jan. 29, p. 193) is a welcome reminder that we must beware of a complacent attitude, developing in some places, towards the therapeutic exploitation of damage to the frontal lobe. I heartily approve his statement that the newest mode of attack is being introduced while we are still struggling to disentangle the results of present methods.

Reckless "advance" at any price, without evidence to justify it, is to be deplored, especially when it involves damaging a vital organ. "Present knowledge of the frontal lobe," he says, "does not as yet permit of advice being given to the neurosurgeon as to what he should destroy." I agree. But is knowledge all that matters? We must not only disentangle the results, we must, as doctors, disentangle the academic and theoretical from the practical and therapeutic. As Professor Alstead has very recently pointed out, "The growth of sub-departments remote from the hospital ward has favoured research which may contribute little or nothing to the immediate requirements of the sick man. Clinicians are becoming increasingly entangled in techniques."¹

If anything, Dr. Glees has understated his case. Not only are we unable to tell the neurosurgeon exactly where to cut, but he as yet, in the blind procedure, cannot be sure of cutting where we ask. More than this, however, no one dare claim to know the mechanism of the major therapeutic effect of leucotomy. It could be a shock effect. If I now suggest that so far as we can be sure at present the advantages of the approach through the orbit are ease of performance, speed, and the lack of necessity for major anaesthesia, then its trial as an alternative to the standard Freeman method is certainly justifiable. I think I am right in saying that there have not yet been reports of the serious physical complications which Dr. Glees lists as possible. If they occur they will be the greatest single contraindication to the new technique. On the other hand, there may be anatomical advantages (or disadvantages), but it will take some time to collect enough information to decide.

In fact, as I am sure Dr. Glees will agree, it will be very long before we know enough about the lobes even for therapeutic purposes. Meanwhile we have to doctor our patients. I think it is in selecting the patients rather than in selecting the cuts that the greatest immediate clinical advance can be made. As a primary objective I should like to see a more careful selection of those patients who will probably benefit

anyway by the blind operation, regardless of just where the cut is made. They will inevitably provide material for studying the effects of slight variations in the incision, and, more important, for even better selection of patients in the future.—I am, etc.,

Runwell, Essex.

P. MACDONALD TOW.

Mechanism of Memory

SIR,—The number of nerve cells in the human brain and spinal cord is fixed before birth. If any die as a result of injury or disease they cannot be replaced. In this respect grey matter differs from many of the other body cells which are replaced regularly. This deficiency carries obvious physiological disadvantages which have recently been thrown into high relief by the work of Knisely.¹ He has shown that during sickness capillaries tend to become choked with sluggish blood corpuscles for a period long enough to bring about the death of the cells they serve. He hints that patches of brain cells may frequently be lost in this manner.

It may be that the inability to replace brain cells accounts for the fact that the human intelligence reaches a limit of development at the age of 17 or thereabouts. It has occurred to me, however, that without this apparent handicap the evolution of man would probably have been impossible.

The mechanism of memory would seem to reside in certain brain cells which in some way must store the nervous impulses they receive from the sense organs. Now it is reasonable to suppose that if these cells were regularly replaced the impressions stored by them would be lost. In that case long-term memory would be impossible. Without memory there could hardly be coherent speech, and therefore there could be no communication of thought.

It may be, then, that the inability of man to regenerate brain cells has been essential to his evolution. This is admittedly academic speculation, but it may prove of interest to neurologists.—I am, etc.,

Farnham, Surrey.

Fluorides and Dental Caries

SIR,—Dr. Alexander MacGregor's letter (Jan. 1, p. 29) admirably summarizes the present position of fluorine in relation to dental caries. But his suggestion that fluorides should not be made available to the public before adequate trials have been performed has its limitations. There cannot be, as he suggests, a similar treatment for fluorides as for penicillin, because fluorides are already available to the public in certain foods and liquids of established use. It is not unreasonable, from the U.S.A. evidence available, to suppose that the proprietary preparations containing fluorides to which he refers are designed to supply about 1 milligram of fluorine a day. From the data¹⁻⁴ on the fluorine content of drinking-water and foods one can obtain an approximate estimate as to how this quantity of fluorine can be taken in a normal manner.

	Average Fluorine Content (parts per million)	Approx. Amount to Supply 1 mg.
Drinking water:		
South Shields	1.4	1.5 pints (738 ml.)
Harrogate	0.6	3 " (1.7 litres)
London (New River) ..	0.35	5 " (2.8 ")
Milk, liquid	0.15	12 " (68 ")
Tea, Indian	40 to 60	2-3 " (1.1-1.7 litres)
Kidney	9	4 oz. (120 g.)
Tinned salmon or sardines	8	4½ oz. (125 g.)
Bone broth	90	½ oz. (15 g.)

The water supplies chosen are comparatively rich in fluorine, since over Britain as a whole there is probably more water drunk with less than 0.3 than more than 0.3 p.p.m.^{1,2} For the foods quoted there is naturally a wide variation, depending on the origin of the material (thus teas are reported to vary from 13 to 180 p.p.m.)³ or the method of preparation (for tea and bone broth particularly).

One must agree, therefore, with Dr. MacGregor that the marketing of tablets, etc., containing fluorine is undesirable in

view of the present lack of information as to their usefulness. But it should be appreciated that the diet and water consumed by many persons has involved for a long time an intake of fluorine similar in form and quantity to that which might arise from the use of fluoride tablets in fluorine-free areas. It is suggested, therefore, that emphasis should be placed on the pursuit of practical trials—of which so far there are few signs in Britain.—I am, etc.,

Lymphoblastic Leukaemia

SIR,—With reference to Dr. D. Pullen's article (Jan. 22, p. 137) on acute lymphoblastic leukaemia treated with urethane, there are several points which I should like to raise.

(1) The dosage of urethane given seems very small. I understand from perusal of the literature that the accepted dose is about 1 g. t.d.s. Creskoff, Fitz-Hugh, and Frost¹ even advise 4 g. per day. (Incidentally this and other references were omitted by Dr. Pullen.) (2) It is not my experience, nor is it that of colleagues (with whom I have discussed this matter), that remissions in acute leukaemia do not last more than a week. (3) A recent case of acute lymphatic leukaemia which came to my notice was treated with urethane, 1 g. t.d.s., for 30 days, and with repeated blood transfusions, with no clinical improvement whatever.—I am, etc.,

Liverpool.

J. G. U. O. ALEXANDER.

Retaining Patency of Veins

SIR,—At the University obstetrics and gynaecological clinic in Budapest the following method is used when giving transfusions in order to ensure that the vein remains patent.

The wall of the vein is gripped with fine artery forceps; a thin thread is led under the vein, and when the needle is inserted in the vein the thread serves to fix it in position. When the transfusion is finished the wall of the vein just distal to the needle is gripped with artery forceps. The thread is cut and the needle is removed. The puncture wound in the wall of the vein can now be seen, and it is seized with a pair of fine Péan's forceps and undertied with a very fine catgut. On removal of the distal pair of forceps the circulation commences without any bleeding from the ligatured part. The wound of the skin is closed with two or three stitches.

Thrombosis rarely occurs in the ligatured vein, because the underlying secures contact of intima with intima, and the vein reacts as if the wall had been very finely sutured. Before removing the needle we inject heparin into the vein to avoid thrombosis due to injury of the vessel. On one occasion the same vein was used to give five transfusions to a patient in three days.

In so far as large veins are concerned our method is not a new one, because it has been applied in surgical institutes for closing the wounds of big vessels, but it is worth considering in the case of small veins. When blood transfusions are necessary every little vein may possess vital importance, and therefore they must be treated with caution. According to our experience this method seems to fulfil the best requirements.—I am, etc.,

Budapest.

GEORGES TANJAN.

POINTS FROM LETTERS

Causes of Rib Fracture

Dr. JAMES T. HAROLD (London, S.W.5) writes: Your issue of Jan. 22 contains references to several unusual causes of rib fracture. Some years ago I encountered another unusual cause. A young female stated that she had once sustained a fractured rib. Knowing her prowess as a huntress I thought it might have been acquired through horse-riding; but this noble animal was not to blame. It transpired that after some months' estrangement from her boy friend she had met him again, was lovingly embraced, and soon after experienced what she described as "a sharp pleuritic pain in the chest." Medical opinion was nonplussed for three days, when an x-ray revealed a fractured lower rib. Could this, Sir, be aetiological ascribed to emotional trauma?

Obituary

SIR EDMUND SPRIGGS, K.C.V.O., M.D., F.R.C.P.

Sir Edmund Spriggs died on Feb. 5 at the Ruthin Castle Clinic with which he had been associated since its creation. Sir Edmund, who had been ill for the last six months, was 77, and his death took place only a few hours after that of his wife.

Edmund Ivens Spriggs was born on Sept. 25, 1871, at Foxton Leicestershire. He was educated at Market Harborough Grammar School and Wycliffe College, Stonehouse. A student at Firth College, which is now the University of Sheffield, he obtained a science scholarship at Guy's Hospital Medical School in 1892. There he graduated M.B. with honours in 1896, proceeding to the M.D. in 1898. In that year Spriggs succeeded F. Gowland Hopkins as demonstrator of physiology under E. H. Starling and afterwards under M. S. Pembrey. Later he was also demonstrator of pharmacology, and he took the M.R.C.P. in 1899. In 1901, while holding the Gull Research Studentship, he worked in Kossel's laboratory at Heidelberg and published then his first paper on peptic activity. Returning to London, he was appointed in 1902 assistant physician to what is now the London Chest Hospital, and in 1903 to the Victoria Hospital for Children, Tite Street. At this time Spriggs was working on diabetes, and he published (with A. P. Beddard and M. S. Pembrey) work confirming the earlier observations of Minkowski and of Kraus.

In the following year, there being no near prospect of a vacancy at Guy's Hospital, Spriggs was appointed assistant physician at St. George's Hospital. He was elected F.R.C.P. in 1905, and in 1906 gave the Oliver-Sharpey lectures on "The bearing of metabolism experiments upon the treatment of disease." Studies of the metabolism of creatinine, made when he was dean of St. George's Hospital Medical School, were followed in 1909 by his first paper on the treatment of gastric ulcer by immediate feeding, the diet being adapted from that of Lenhartz. This method, with modifications, Spriggs used in suitable cases from that time onwards.

At the end of 1911 Edmund Spriggs had an illness which continued for fifteen months. He was advised not to return to London and was offered by Dr. David Lawson the post of senior physician at a new clinic for gastric disorders. This was accepted on the stipulation that the range of work should comprise internal medicine as a whole and that the clinic should be provided with suitable laboratories and scientific staff. The new clinic was conducted for ten years at Duff House, Banff, Scotland, and then moved to Ruthin Castle, North Wales. In 1917-18 Spriggs acted as medical adviser to the Ministry of Food, and was a member of the rationing committee. After the war he wrote the first of a succession of papers with O. A. Marxer on diverticulosis and diverticulitis. In 1923, with D. V. Pickering and A. J. Leigh, Spriggs recorded one of the earliest cases, if not the earliest in this country, of severe diabetes treated with insulin. A few years later (with J. H. Anderson) he was able to describe the recovery of the first two cases of pernicious anaemia treated in this country with the Minot-Murphy liver diet. Other papers which appeared later had been presented as opening addresses at medical meetings at Winnipeg in 1930 and at Wellington, New Zealand, in 1937.

[Elliott and Fry, Ltd.]

in the Croonian Lectures in 1933 Spriggs reviewed 500 cases of headache. As recently as 1943 he wrote for the *Quarterly Journal of Medicine* a paper on polyps of the stomach and polypoid gastritis.

In a long and busy life Sir Edmund, as he became in 1935, published over a hundred papers. Out of doors his recreations were walking, fishing, shooting, and the breeding and training of retrievers; his Yellow Labradors competed with success in field trials.

He became a J.P. in Banffshire in 1919 and in Denbighshire in 1929. His two sons are both doctors, and the sympathy of all his friends and colleagues will be extended to them.

SIR FREDERIC J. WILLANS,
K.C.V.O., M.R.C.S., L.R.C.P.

Sir Frederic J. Willans died at his home in Sandringham on Jan. 27. He had held the post of surgeon-apothecary to his Majesty's Household at Sandringham since 1924, and had also been surgeon-apothecary to Queen Alexandra.

Frederic Jeune Willans, eldest son of the late Dr. W. Blundell Willans, was born at Much Hadham, Hertfordshire, in 1884. He was educated at Framlingham College, and at Durham University and the London Hospital, qualifying M.R.C.S., L.R.C.P. in 1910. Except for four years' service with the R.A.M.C. during the 1914-18 war, the whole of his active career was spent in general practice at Sandringham. He became surgeon-apothecary after the death of the first holder of the appointment to King Edward VII, Sir Alan Manby, whose assistant he was. In the course of his long and devoted service Willans had probably been consulted by members of the royal family more often than any other member of the profession; on many occasions he was the first medical man to be called in attendance. He was awarded the M.V.O. in 1923, promoted to C.V.O. in 1925, and created K.C.V.O. in 1933.

Sir Frederic was very popular among his many friends and patients in the Sandringham district, and although he had not been in good health for the past year his death after only a week's illness came as a shock to many. Always an active member of the British Medical Association, he was chairman of the West Norfolk Division in 1925-6 and chairman of the Norfolk Branch in 1936-7. During the recent war he presided over the King's Lynn district medical board. He married, in 1916, Wynfred, the only daughter of the late Sir Alan Manby. There were no children.

An intimate friend has written: Not every man who has walked a hospital "can walk with kings, nor lose the common touch." Called very early in his medical career to minister at the bedside of royalty, Frederic Willans was nevertheless beloved by all the people of the villages on the estate which has for its centre Sandringham House. A keen cricketer, he once captained the Sandringham side. He was also an excellent tennis player, and he enjoyed his golf almost to the last. He was, too, an ardent philatelist. A warden of his parish church, he took a keen interest in the life of West Newton, where he lived. He had a real sense of humour, and children loved him. His heart, however, was in the work to which he gave himself with unsparing energy until a few days before his death. Since last summer he had known the serious nature of the condition which was to prove fatal, though with characteristic bravery and thought for others he concealed this from even his most intimate friends. In the country it sometimes happens that a man lives and works for so long in one place, and becomes so familiar a part of the village scene, that it seems he must always be there. His neighbours will find it difficult to imagine life without him. His tall, spare figure will be sorely missed by many, and especially in those hours of joy and sorrow when men and women find in their doctor the strength and help that no one else can give. Every agricultural worker knew that "Sir Frederic" would come to his aid at any hour of the day or night and with painstaking care give him as much attention as he gave to the highest in the land. The large congregation at his funeral was a remarkable testimony to the esteem and affection in which he was held among all sorts and conditions in the neighbourhood where he had practised for thirty-five years.

F. H. A. MARSHALL, C.B.E., F.R.S.

Dr. F. H. A. Marshall, who was for many years reader in agricultural physiology in the University of Cambridge, died suddenly after an operation on Feb. 5. Dr. Marshall, who was 70, had lectured on the physiology of reproduction to several generations of medical students at Cambridge.

Francis Hugh Adam Marshall was born at High Wycombe on July 11, 1878, and was educated at St. Mark's School, Windsor, and privately. He went up to Christ's College, Cambridge, in 1896 from University College, London. He took the Natural Science Tripos three years later and then went to Edinburgh to work as a research student with Professor Cossar Ewart. Later he was Carnegie Fellow and lecturer on the physiology of reproduction in the University, and it was only in 1908 that he returned to Cambridge as lecturer in agricultural physiology. He was a proctor in 1911-12, and subsequently served on the council of the Senate. Dr. Marshall continued as lecturer in physiology for more than thirty-five years until 1943, and for a short time he succeeded Professor T. B. Wood as director of the Institute of Animal Nutrition. He was successively fellow, tutor, dean, and, in 1940, vice-master of Christ's College. Dr. Marshall assisted Cossar Ewart with his experiments on telephony, and this stimulated his interest in the physiology of reproduction. He went on to study the oestrous cycle in sheep, in the ferret, and in the dog. The last of these studies led to the preparation of a paper written in collaboration with Professor W. A. Jolly and entitled "The Ovary as an Organ of Internal Secretion." Other papers were concerned with the effects of the removal and transplantation of the ovaries and with the part played by the Graafian follicle in the initiation of oestrus. Marshall's *The Physiology of Reproduction* was first published in 1910; the second and much enlarged edition appeared in 1922, and the third edition was published only last year.

H. A. RICHARDS, M.R.C.S., D.A.

Dr. Hugh Richards, consulting anaesthetist to King's College Hospital, died on Jan. 22 while on holiday at Grenada, British West Indies. Educated at Rossall and Clare College, Cambridge, he qualified from King's College Hospital in 1913. At the beginning of the 1914-18 war he was holding an appointment as ship surgeon in the Orient line, and he continued for a time as surgeon in charge of troopships. Later he went to France, and until his demobilization served in a casualty clearing station. There he first became interested in anaesthetics. In 1921 he was appointed to the honorary staff of King's College Hospital as an anaesthetist, and in 1935 he became senior anaesthetist, which post he held until his retirement in 1946. He was given the D.A. in 1936, and only last year was awarded the fellowship of the recently formed Faculty of Anaesthetists of the Royal College of Surgeons. He was also an active member of the Royal Society of Medicine, acting in the Section of Anaesthetists as secretary and later as president. In September, 1939, he gave up his private practice to take up a full-time appointment in the Emergency Medical Service, and throughout the war he worked at Horton Emergency Hospital, where he not only took a full share in the routine work but was largely responsible for the organization of the anaesthetic services and continued to teach students and to train residents.

Throughout his life Hugh Richards saw only the right way and the wrong way. He adhered unhesitatingly to the principles he had laid down for himself and expected others to do the same. His bluff and uncompromising manner prevented some from looking beneath the surface, but those who did so found a character of sincerity and great loyalty. Once given, his support was never withdrawn from one he found worthy of friendship. He was essentially a King's man, and he served his hospital ungrudgingly from his time as a student until his retirement. He gave ether in a masterly fashion, and with it he obtained results which he claimed, with some justification, were equal to those of any other method; it had served him as a friend for many years and he was not easily led away by more recent methods. As a teacher he had exceptional ability, and he taught with zeal. His instruction was firm and dogmatic, and he taught mainly those fundamental principles which the undergraduate should know. He was intolerant of stupidity

and lack of attention to detail, and did not hesitate to use biting sarcasm; but this was only a part of his well-tryed method. His students learnt fast, and when they had finished their course with him they had a firm foundation on which to build in the future. He had a great interest in all student activities; during his early years on the staff he had much to do with reviving the hockey club, and he continued to support both it and the rugby football club until he retired. He was for many years treasurer, and for the last five years president, of the students' clubs and societies union, and his able management served this organization well.

Dr. Richards married just before he left the staff, and his friends thought he was assured of many years of contented retirement. By his unexpected death many of his colleagues have lost a generous friend and King's College Hospital has lost one of its most loyal supporters.

Medico-Legal

MEASLES IN A HOTEL

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A prospective guest who had booked rooms for his family cancelled his booking when he heard that a child in the hotel had measles. The proprietor sued him for breach of contract, claiming £72, but the learned judge of Bournemouth County Court, Judge A. H. Armstrong, ruled that the prospective guest had been right and dismissed the suit. A guest at a hotel is an invitee, and therefore has a right to be secured against harm. The duty to make premises safe is even more stringent when a child is a possible sufferer.

1 Evening Standard, Nov. 24, 1948.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation on Jan. 20, the following medical degrees were conferred:

M.D.—F. Hampson.
M.B.—T. Bell, D. G. Jamison, *J. T. H. Green, *T. H. C. Lewis, *A. H. Campbell

* *In absentia.*

UNIVERSITY OF CAMBRIDGE

Sir Edward Mellanby, F.R.S., Secretary of the Medical Research Council, will deliver a lecture in the Physiological Laboratory Theatre on Friday, Feb. 25, at 5 p.m. His subject is "An Experimental Investigation into a Condition of Widespread Nerve Degeneration." The lecture is open to members of the University without fee.

UNIVERSITY OF MANCHESTER

The University Council has appointed R. S. F. Schilling, M.D., to be Reader in Occupational Health.

UNIVERSITY OF BRISTOL

The following candidate has been approved at the examination indicated:

M.D.—J. B. Brierley.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a meeting of the College, held on Feb. 1, with Dr. W. D. D. Small in the chair, the following were elected to the Fellowship: R. G. McInnes (Oxford), K. M. Morris (Edinburgh), W. J. Burns (Edinburgh).

The Diploma of Membership was conferred upon the following: W. G. Greene (Chester), F. O'D. Finnigan (London), R. Natarajan (Deolali, India), Siva R. K. Padmavati (Coimbatore, India), J. M. Barber (London), F. G. Patrick (King's Lynn), A. M. Merriweather (Bechuanaland), R. E. Beamish (Winnipeg), R. P. Gillespie (Edinburgh), S. P. Hall-Smith (Hove), J. R. Mackenzie (Carlisle), I. H. Stokoe (Edinburgh), R. M. Marquis (Edinburgh), D. H. Reilly (Quebec), J. Williamson (East Kilbride), A. W. B. Cunningham (Edinburgh), R. G. Mitchell (Edinburgh), Alwyne B. Gordon (Sydney), R. A. Bustamante (London), G. L. Brinkman (London).

Medical Notes in Parliament

Remuneration for Temporary Residents

On Feb. 3 Colonel STODDART-SCOTT asked the Minister of Health if any payments had yet been made to the doctors in the National Health Service for the treatment of temporary residents, visitors, holiday-makers, foreigners, and those patients not on a doctor's list.

Mr. BEVAN replied that no payments had yet been made for the treatment of temporary residents, visitors, holiday-makers, and foreigners. The principles on which such payments should be made were under discussion with the medical profession. It was contemplated that payments in respect of the period from July 5 to Dec. 31, 1948, should be made on March 31 next. The amount of these payments was not yet known. So far as he knew, this country was at present the only one which provided such a service for its visitors.

Refresher Courses

During the period July 5, 1948, to Jan. 31, 1949, payment in respect of refresher courses under Section 48 of the National Health Service Act amounted to £1,335. In the same period payments amounting to £1,982 were made in respect of refresher courses for ex-Service doctors and dentists. There were in addition a large number of residential and other appointments in hospital for ex-Service doctors.

Fees for Sight-testing

Replying on Feb. 3 to Sir GEORGE HARVIE WATT, who asked what fees were payable to persons included in the ophthalmic list for services rendered under the National Health Service Mr. BEVAN replied that the fees were:

	£	s.	d.
Ophthalmic medical practitioners, sight testing fee ..	1	11	6
Ophthalmic opticians, sight-testing fee	15	6
Ophthalmic or dispensing optician, dispensing fee ..	1	5	0

He added that any proposals to adjust these amounts were matters for discussion with the professional organizations and with the Optica Whitley Council as regards opticians.

Radioactive Effluent

Mr. BOYD-CARPENTER asked on Feb. 3 what steps were taken to check the degree of radioactivity of material in the River Thames resulting from the discharge of radioactive effluent from Harwell. Mr. BEVAN explained that each batch of effluent was tested and certified at Harwell before discharge into the Thames and the total amount of radioactive material discharged was always known at Harwell and by the Ministry of Health. The amount which could be discharged with safety had been determined on the recommendations of a scientific subcommittee of the Medical Research Council. The amount so far discharged had been much below that safety limit, and would probably be too small, after dilution with river water to be detected at all. Tests of the river water would not therefore at present be of any value.

Milk Bill

At a meeting of the Parliamentary Medical Group at the House of Commons on Feb. 3 the officers of the Group were reappointed for 1949. The Milk (Special Designations) Bill was discussed with a deputation from the British Medical Association, and it was agreed to seek certain amendments. The Bill has already passed through the Committee and Report stages in the House of Lords.

Single-handed Doctor

Mr. MARTIN LINDSAY asked on Feb. 3 how many people received E.C./Reg.107, dated Jan. 14, from the Birmingham Executive Council informing them that they must change their doctor.

Mr. BEVAN said in reply that the executive council's letter of Jan. 14 was sent to 3,196 people. They were all on the list of a single-handed doctor whose total list amounted to 8,275 or over double the number agreed with the medical profession as the maximum which could be properly attended by one doctor. The action was taken in consultation with the doctors concerned. Mr. Bevan saw no reason to question it.

better technique

in the investigation of STERILITY

Designed mainly for the investigation of sterility, 'Visco-Pyelosil' eliminates many of the shortcomings encountered with earlier contrast media. 'Visco-Pyelosil' is a 35 per cent aqueous solution of diiodone and, by virtue of its viscosity, has far less tendency than ordinary solutions to run back between the cannula and the cervix, thus the risk of the picture being obscured by leakage of the medium into the vagina is very appreciably reduced. Because 'Visco-Pyelosil' is rapidly absorbed, there is no chance of chronic irritation resulting from its retention in the body cavities. Moreover, the preparation is free from toxicity even in much larger doses than those employed in practice. Exposures are made immediately after the injection of 'Visco-Pyelosil' and the resultant pictures are of high density and excellent definition, readily revealing any abnormality of the fallopian tubes.

TEMPORIS ARS MEDICINA PERE EST (OVID)

The art of medicine is generally a question of time. With the peptic ulcer patient, as is well known, the rate of healing is determined by the ulcer's freedom from irritation. By rapidly buffering excess acid and at the same time avoiding acid rebound, 'ALUDROX,' a suspension of 5.6% colloidal aluminium hydroxide in gel form, ensures rest for the ulcer. Pain is relieved and time taken for healing reduced to a minimum.

Wyeth

Nitrogen Mustard Hydrochloride- Boots

A POWERFUL cytotoxic agent which in carefully controlled dosage acts selectively against cells showing increased proliferative activity. Clinical trials have shown that the intravenous injection of Nitrogen Mustard Hydrochloride will reduce the tumour masses in cases of Hodgkin's disease that have become resistant to X-rays, and will bring about a fall in the white cell count in some cases of chronic myelogenous leukaemia. It is also of value in the reticuloses and in some cases of lymphosarcoma.

Boxes of 10 x 10 mg. rubber-capped vials.

A COLLOID OF FERRIC HYDROXIDE (10% Fe) One teaspoonful is equivalent, in iron content, to approximately 30 grs iron and ammonium citrate.

Neo-Ferrum is an inexpensive and highly effective form of iron suitable for general use in the treatment of iron deficiency anæmias. It is pleasantly flavoured and does not upset the stomach nor discolour the teeth.

Neo-Ferrum Tablets provide an extremely convenient and pleasant alternative; two tablets are equivalent to one teaspoonful of the liquid product.

Neo-Ferrum may be given to young infants as well as to children and adults. The liquid preparation is readily miscible with milk feeds.

relief... in asthma

CONSCIOUS or unconscious fear of an attack often shadows the mind of the asthmatic. The knowledge that he has 'Franol' to forestall or relieve such attacks can dispel this shadow and restore confidence.

'Franol' is a potent combination of ephedrine (to relieve bronchial spasm), theophylline (to dilate the bronchioles) and 'Luminal' (to mitigate apprehension).

At the first warning of an attack, two tablets of 'Franol' will often bring relief. Taken regularly, 'Franol' will bring an all-round improvement in the general condition.

Medical literature supplied upon request

Tablets in tubes of 20 bottles of 100, 500, 1,000

For chilblains 'PERNIVIT'

Tablets of Acetomenaphthone
and Nicotinic Acid B.D.H.

Considerable success in the treatment of chilblains has been reported following the use of acetomenaphthone in one group of patients and of nicotinic acid in a second group.

It may be that abnormal venous permeability and prolonged blood clotting time on the one hand and venous stasis from vasoconstriction on the other are both contributory causes of chilblains.

Trial of a combination of acetomenaphthone and nicotinic acid collaterally, therefore, seems justified. 'Pernivit' is now available as tablets, each containing

Acetomenaphthone 7 mg.
(Prokayvit Oral)

Nicotinic Acid 25 mg.
Bottles of 50 and 500 tablets

Nursing Staff

Asked on Feb. 3 to give the number of nursing staff employed in hospitals at any convenient date in 1938, 1946, and 1948, Mr. BEVAN furnished these figures:

September, 1938—96,800 (including 800 part-time).
September, 1946—111,600 (including 2,600 part-time).
September, 1948—132,000 (including 19,000 part-time).

He added that the number of hospital beds unstaffed in September, 1948, was 57,000, or about one-ninth of the total number of beds.

Parliamentary Secretary.—Mr. ARTHUR BLENKINSOP, hitherto Parliamentary Secretary to the Ministry of Pensions, has been appointed to be Parliamentary Secretary to the Ministry of Health in place of Mr. L. J. Edwards, who becomes Parliamentary Secretary to the Board of Trade.

EPIDEMIOLOGICAL NOTES

Influenza

There were 37 deaths from influenza in the great towns of England and Wales in the week ended Jan. 29, as against 45 in the preceding week. In the first four weeks of 1949 the deaths were, on the whole, lower than they had been in any previous year except 1948.

There have been several reports of scattered outbreaks of influenza in camps and residential schools. This appears to be true influenza, and virus has been isolated from some cases. Generally speaking the disease is usually mild, with fever lasting about four days. The current English strain has not yet been finally identified, but one French and two Dutch strains seem to be identical serologically and related to, but not identical with, the English 1947 A. All these strains are remotely related to the PR8 strain of virus A.

Discussion of Table

In England and Wales increases were reported in the notifications of scarlet fever 322, whooping-cough 117, diphtheria 39, and dysentery 34. There was a decrease in the incidence of measles 668 and of acute pneumonia 134.

The decreased incidence of measles was due to the experience of the northern part of the country; in the south an increased incidence was recorded. The largest decreases in the notifications of measles were Lancashire 398, Yorkshire West Riding 228, and Gloucestershire 198; the largest increases were Southampton 251, Essex 119, and Surrey 60.

A small rise in the incidence of scarlet fever occurred throughout the country; the largest rises were Lancashire 108 and Yorkshire West Riding 55. With a few exceptions the local returns for whooping-cough showed only slight fluctuations; there was a rise of 37 in Surrey and a fall of 40 in Leicestershire.

The chief feature of the returns of diphtheria was an increase of 21 in Yorkshire West Riding; this was mainly due to an outbreak affecting 15 persons in Bradford C.B. Notifications of diphtheria in the south-eastern counties rose from 4 to 11.

An outbreak of dysentery with 5 cases was notified from Oxford, Bullington R.D. The largest returns for dysentery were London 41 (St. Pancras 31); Lancashire 24 (Liverpool C.B. 8, Oldham C.B. 8); and Yorkshire West Riding 8.

There were multiple notifications of acute poliomyelitis in London 3 (Islington 2); Middlesex 2; Gloucestershire (Bristol C.B. 2); Nottinghamshire (Bassetford R.D. 2); Lancashire 2, and Yorkshire West Riding 2.

In Scotland there were decreases in the notifications of whooping-cough 56 and measles 45, with a rise in the incidence of scarlet fever 15 and diphtheria 13. The notifications of scarlet fever declined by 17 in the western area but rose in the remaining areas.

In Eire the notifications of diarrhoea and enteritis increased by 17 and the notifications of measles declined by 16. The increase in cases of diarrhoea and enteritis was due to the experience of Dublin C.B.

In Northern Ireland an increase was recorded in the notifications of scarlet fever 16 and measles 12. The incidence of measles rose in Belfast C.B. 19 and Antrim County 15, and fell in Tyrone County 31.

Week Ending January 29

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,191, whooping-cough 2,857, diphtheria 141, measles 11,656, acute pneumonia 935, cerebrospinal fever 45, acute poliomyelitis 20, dysentery 60, paratyphoid 2, and typhoid 3.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Jan. 22.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases, a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

¶ Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

Medical News

Lord Webb-Johnson

Lord Webb-Johnson, President of the Royal College of Surgeons of England, has been made an Honorary Freeman of the Worshipful Company of Barbers, whose Master is Dr. G. G. Macdonald. The ceremony conferring the freedom took place at a recent meeting of the Court.

N.A.P.T. Colonial Scholarships

The National Association for the Prevention of Tuberculosis has decided to offer six further scholarships for postgraduate study in tuberculosis in Britain during 1949. They will be open to doctors and other medical personnel of either sex throughout the British Colonial Empire and the Sudan. The successful candidates will come to Britain for about six months to study tuberculosis in its widest aspects—preventive, clinical, administrative, and social. The awards are as follows: (a) two scholarships to doctors who either possess qualifications registrable in the United Kingdom (value of scholarships, £120 each) or are graduates of Colonial Medical Schools (value of scholarships, £100 each); (b) four scholarships (value £80 each) to matrons, nurses, health visitors, or members of Colonial Sanitary Departments. The successful candidates will be granted allowances to cover lodging and subsistence expenses from Colonial Government funds, and the details of their training during the tenure of the scholarship will be supervised by the N.A.P.T. Travelling expenses, purchase of books, and other incidental expenditure will fall to be met by scholars out of their scholarship money. Application, which should be made through heads of departments, will be forwarded to the Colonial Office, which will make recommendations to the Council of the N.A.P.T. Candidates should submit applications in time for them to reach the Colonial Office by May 1.

Infected Meat

The National Veterinary Medical Association has issued a warning to the public against buying uncooked meat at pet-food shops. Some of the meat may have been condemned as unfit for human consumption on account of its being infected with tuberculosis or other disease. There is an obvious danger of dogs and cats contracting the disease from this source unless the meat is thoroughly cooked; and the danger to animal owners handling such meat before it is cooked is said to be by no means negligible. Where such meat has to be handled raw, it is advisable to wash the hands thoroughly afterwards. One Cuy Corporation, on the advice of its Chief Veterinary Officer, has already obtained from Parliament authority to make by-laws to protect the public from this danger.

Hospital Catering Training Centre

A training centre for training in all branches of hospital catering is to be established under the auspices of King Edward's Hospital Fund at St. Pancras Hospital (now part of University College Hospital). The centre will provide meals for patients and staff in the hospital, be a model catering department in layout, organization, and equipment, and include all modern labour-saving devices. It will be at least six or twelve months before it is ready to take trainees. Mr. C. C. A. Gibbs has been appointed officer-in-charge of the centre. He was formerly catering officer to St. Mary's Hospital.

New Pharmaceutical Preparations

In order to help medical practitioners and pharmacists the *Pharmaceutical Journal* has started a service giving information about new proprietary and non-proprietary preparations. For two guineas a year the subscriber receives cards on which the preparations are described—their composition, indications for use, dosage, packing and price, and suppliers. References in the medical press on the use of some of the preparations are included. A filing cabinet for the cards is supplied. Information may be obtained from the *Pharmaceutical Journal* (Department N.P.), 33, Bedford Place, London, W.C.1.

National Insurance Scheme

Employed and self-employed new entrants to the National Insurance scheme on July 5, 1948, who were ill during the first six months of the scheme and, because they were not entitled to sickness benefit or for some other reason, did not notify the local National Insurance Office of their incapacity are advised by the Ministry of National Insurance to do so as soon as possible. If the local National Insurance Office is notified of incapacity, contributions can be excused in certain circumstances, even though the insured person is not entitled to benefit. Until a contribution is excused, however, an insured person remains liable to pay a contribution for each week he is sick and not receiving benefit.

Ipswich and Colchester Rahere Club

At a meeting held at Colchester on Jan. 8 under the chairmanship of Dr. Penry Rowland a Rahere Club was formed, open to old students of St. Bartholomew's Hospital in Suffolk and North Essex. The next dinner will be held at Ipswich in October. The secretary, Dr. W. Radcliffe, Wivenhoe, near Colchester, will be glad to hear from any old Bart's students in the district who may be interested.

COMING EVENTS

Liverpool University Medical Students' Society

The annual dinner of the Liverpool University Medical Students' Society will be held at Exchange Hotel, Liverpool, on Wednesday, Feb. 23, at 7 for 7.30 p.m., when the guest of honour will be Sir William Gilliat.

Swiss Medical Congress

The 17th Annual Congress of the Swiss Society of Internal Medicine will be held at Lugano on May 6-8. Information may be obtained from Dr. O. Gsell, Kantonsspital St. Gall, Switzerland.

International Congress of Electroencephalography

The second International Congress of Electroencephalography will be held in Paris on Sept. 1, 2, and 3, and on one day of the following week there will be a joint meeting with the International Neurological Congress. Full particulars may be obtained from the British representative on the organizing committee of the congress, Dr. W. Grey Walter, Burden Neurological Institute, Stoke Lane, Stapleton, Bristol.

N.A.P.T. Jubilee

The National Association for the Prevention of Tuberculosis will celebrate its jubilee this year by holding a Commonwealth and Empire Health and Tuberculosis Conference on July 5-8. The provisional programme is as follows: Tuesday, July 5: "Tuberculosis as a World Problem—Trends in the Modern Treatment for Tuberculosis, including Streptomycin and P.A.S." Wednesday, July 6: "Regional, County, and County Borough Tuberculosis Schemes—Organization of Comprehensive Tuberculosis Schemes in a British Colony." Thursday, July 7: "Problems in the Prevention and Detection of Tuberculosis, (a) Tuberculosis among Nurses and Students, (b) The Policy of B.C.G. Administration—Psychological and Social Readaptation of Chronic Disease in Industry." Friday, July 8: "Protection from Bovine Tuberculous Infection." Speakers will include: Dr. Marc Daniels, Dr. T. A. Lloyd Davies, Dr. John Francis, Professor Jorgen Lehmann, Dr. Geoffrey Marshall, Dr. John G. Scadding, Mr. C. Price Thomas, Dr. Charles Wilcocks, Dr. A. B. Williamson, Dr. J. Greenwood Wilson. The fees are three guineas for four days, one guinea for a single day or session. Particulars may be obtained from the N.A.P.T., Tavistock House North, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

Monday

LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, London, W.C., Feb. 14, 4.45 p.m. "The Ultracentrifuge and Electrophoresis Apparatus in Protein Research," by Dr. P. Johnson, Ph.D.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, London, W., Feb. 14, 8.30 p.m. "Old Age." Discussion to be introduced by Dr. Trevor Howell and Mr. W. Sampson Handley.

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Feb. 15, 5.15 p.m. "Diseases of the Nails," by Dr. I. Muende.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Feb. 15, 11 a.m. "Urethritis due to Protozoa, Metazoa and Fungi," by Dr. A. H. Harkness.

LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, London, W.C., Feb. 15, 5.15 p.m. "Anatomical and Histological Correlations," by Dr. A. Schweitzer.

ROYAL COLLEGE OF PHYSICIANS, LONDON, Pall Mall East, S.W.—Feb. 15, 5 p.m. "Tuberculosis in Post-war Europe," Milroy Lecture by Dr. Marc Daniels.

Wednesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Feb. 16, 5 p.m. "X-ray Technique," by Dr. C. W. McKenny.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Feb. 16, 11 a.m. "Urethritis due to Protozoa, Metazoa and Fungi," by Dr. A. H. Harkness.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury Square, London, W.C.—Feb. 16, 7.30 p.m. "The National Formulary, 1949," by Mr. T. C. Denston, B.Pharm., Ph.C., F.R.I.C.

ROYAL MICROSCOPICAL SOCIETY.—At B.M.A. House, Tavistock Square, London, W.C., Feb. 16, 5.30 p.m. Ordinary meeting. "Reflecting Microscopes—Past, Present, and Future," by Dr. R. Barer.

Thursday

EDINBURGH CLINICAL CLUB.—At B.M.A. Scottish House, 7, Drumshugh Gardens, Edinburgh, Feb. 17, 8 p.m. "Functional Disorders of Childhood," by Dr. J. L. Henderson.

EDINBURGH ROYAL INFIRMARY.—Feb. 17, 5 p.m. "Incoordinate Uterine Action." Honyman Gillespie Lecture by Dr. Clifford Kennedy.

FACULTY OF RADIOLOGISTS.—At British Institute of Radiology, 32, Welbeck Street, London, W., Feb. 17, 8.15 p.m. Joint meeting with British Institute of Radiology and R.S.M. Section of Radiology. "The Physical, Cytological, and Medical Aspects of Protection from Ionizing Radiations with Special Reference to the Use of High Voltage X Rays and Radio-isotopes." Discussion to be opened by Sir E. Rock Carling, and Professor W. V. Mayneord.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Feb. 17, 11 a.m. "Traumatic Urethritis," by Dr. A. H. Harkness.

LONDON UNIVERSITY.—At Large Lecture Theatre, St. George's Hospital Medical School, Hyde Park Corner, London, S.W., Feb. 17, 4.30 p.m. Lecture-demonstration: "Psychiatry."

LONDON: UNIVERSITY COLLEGE.—At Anatomy Theatre, Gower Street, London, W.C., Feb. 17, 1.15 p.m. "The New Philosophy of Science," by Dr. G. Burniston Brown.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Feb. 17, 5 p.m. "Tuberculosis in Post-war Europe," Milroy Lecture by Dr. Marc Daniels.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At 26, Portland Place, London, W., Feb. 17, 7.30 p.m. "The Epidemiology of Yellow Fever in Central Africa," by Dr. A. F. Mahaffy. A discussion will follow.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At B.M.A. House, Tavistock Square, London, W.C., Feb. 17, 5.30 p.m. "Can the M.O.H. Help to Prevent Accidents in the Home?" Paper by Dr. C. A. Boucher, to be followed by a discussion.

Friday

BIOCHEMICAL SOCIETY.—At St. Thomas's Hospital Medical School, London, S.E., Feb. 18, 2 p.m. 274th meeting. Papers will be read.

FACULTY OF RADIOLOGISTS.—Joint meeting with British Institute of Radiology and R.S.M. Section of Radiology, Feb. 18. Discussion: "The Physical, Cytological, and Medical Aspects of Protection from Ionizing Radiations with Special Reference to the Use of High Voltage X Rays and Radio-isotopes." (1) At Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., 2.15 p.m. To be opened by Drs. J. R. Nuttall, J. F. Loutit, and A. Glucksmann. (2) At Royal Society of Medicine, 1, Wimpole Street, London, W., 8.15 p.m. To be opened by Sir E. Rock Carling and Drs. Katharine Williams and W. G. Marley.

LONDON CHEST HOSPITAL, Victoria Park, E.—Feb. 18, 5 p.m. "The Place of Ear, Nose, and Throat Surgery in the Treatment of Chest Diseases," by Mr. J. W. S. Lindahl.

MIDDLESEX COUNTY MEDICAL SOCIETY.—At Edgware General Hospital, Edgware, Middlesex, Feb. 18, 3 p.m. General meeting.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh—Feb. 18, 8 p.m. "Lobar Pneumonia," by Mr. G. F. A. Howie.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At South Kensington Hotel, 41, Queen's Gate Terrace, London, S.W., Feb. 18, 7.15 for 7.30 p.m. Dinner meeting 8.30 p.m. "Guild for Doctors," by Lord Horder.

Saturday

KENT PAEDIATRIC SOCIETY.—At Royal Star Hotel, Maidstone, Feb. 19, 2.30 p.m. "The Children's Act," by Dr. Dorothy Makepeace and Miss Harvie.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Arnott.—On Jan. 23, 1949, in London, to Dr. Ruth Arnott (née Burt), wife of Dr. D. C. Arnott, twin sons.

Baker.—On Feb. 3, 1949, at County Hospital, Hereford, to Bobbie (née Gelder), wife of Dr. W. H. J. Baker, a daughter.

Jones.—On Jan. 30, 1949, at Swiss Cottage, Llanelly, to Margaret (née Penny), wife of Dr. Derek Hayman Jones, a daughter.

Lamming.—On Jan. 10, 1949, to Olive (née Callow), wife of Robert L. Lamming, F.R.C.S., Douglas, Isle of Man, a daughter.

Pitt.—On Jan. 12, 1949, in Watford, to Penelope (née Reynolds), wife of Dr. N. P. Pitt, a daughter.

Tate.—On Feb. 1, 1949, at Nottingham Hospital for Women, to Margaret (née Bailey), wife of Malcolm Tate, B.M., of Bredon, Oak Tree Lane, Mansfield, a son—Philip.

MARRIAGE

Ballet—Gibson.—On Jan. 15, 1949, at Gorings-by-Sea, Worthing, John Ballet, M.B., B.Ch., to Jean Gibson, M.R.C.S., L.R.C.P.

DEATHS

Bateman.—On Jan. 30, 1949, at Chester Military Hospital, Albert Brooke Bateman, V.D., M.B., Ch.B., B.D.S., L.D.S.R.C.S., Surgeon Commander (D), R.N.V.R.

Bertram.—On Feb. 2, 1949, at Nantbank, Taymull, Arxill, William Darling Bertram, M.B., Ch.B., D.P.H., aged 47.

Bleasby.—On Feb. 1, 1949, at Sunderland General Hospital, Doris Eliza Bleasby, L.R.C.P.S.Ed., of Glasgow, aged 29.

Galbraith.—On Feb. 1, 1949, at Ross Memorial Hospital, Dingwall, James John Galbraith, M.D., D.P.H., J.P., aged 71.

Haldin-Davis.—On Feb. 2, 1949, at Greens End, Forest Row, Sussex, H. David Haldin-Davis, M.D., F.R.C.P., F.R.C.S., late of 52, Harley Street, London, W.

Hayles.—Recently, Alfred William Hayles, M.R.C.S., of Postnewydd, near Newport, Mon., aged 85.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Hereditary Influence of Epilepsy

Q.—Is there any evidence that the children of an epileptic are specially liable to nervous or other affections?

A.—Hereditry is undoubtedly an important factor in the aetiology of epilepsy. Some studies have shown that as many as 10% of children with an epileptic parent are similarly affected. It seems likely, however, that this high figure is true only for institutional and severe cases, in which the hereditary component is strongest. Samples drawn from the general population, and thus including milder instances, give a lower figure—perhaps not much more than 2½%. Nevertheless this last figure is about five times greater than the general incidence of the condition. It is difficult, in the light of present knowledge, to be at all sure whether epilepsy should be regarded as one thing or many, speaking genetically. There is evidence that traumatic epilepsy is more likely to develop in those with a hereditary predisposition. The electroencephalographic studies of Lennox and Gibbs indicate that about 5% of the population show abnormal brain waves: it is suggested that the underlying condition behaves as a Mendelian dominant; it has also been found that identical twins always resemble each other in the presence or absence of abnormal rhythm and also in its type. Of the 5% who are predisposed, however, only about 1 in 20 ever has fits. Whether predisposition results in the manifest condition is presumably determined, or largely determined, by environmental influences. Thus, although the brain waves of identical twins are always alike, such twins not infrequently differ as regards actual epilepsy. It has also been observed that fraternal twins are considerably more alike in this respect than are brothers and sisters born at different times; presumably this points to the importance of prenatal or natal influences. Further research will be required before it becomes possible to elucidate the inheritance of epilepsy more precisely and also to calculate reasonably accurate chances in individual instances.

It would not appear that epilepsy is often genetically associated with other neurological and mental abnormalities, though some writers have claimed a connexion with migraine. The epilepsy which is so common in low-grade mental defectives is a special case; this is something different in its causation from the epilepsy occurring in those of normal mentality, and epileptic mental defectives do not appear to have any excess of epileptic relatives.

Water-Pitressin Test in Epilepsy

Q.—May I have full details of the water-pitressin test used as an aid to diagnosis in doubtful cases of epilepsy?

A.—The patient is confined to bed throughout the test. He is given an enema, is asked to pass urine, and is then weighed. He is fed on an ordinary diet with copious fluids. The intake and output of fluid are measured and are charted daily, and the patient is weighed morning and evening. An increase of 2% in the body weight with an excess of intake over output is taken as proof that a positive water balance has been established. This point is usually reached in 48 hours. Pitressin 0.25 ml. is then given intramuscularly, and 300 ml. of water by mouth. Further doses of pitressin (0.5 ml.) are given with 300 ml. of water every two hours to a total of ten injections unless a fit occurs before, when the test is stopped. Positive results have been claimed in from 40 to 80% of suspected epileptics, and there appears to be no risk of causing a fit in a person who is not an epileptic. Pitressin should not be administered to patients suffering from diabetes mellitus, nephritis, arteriosclerosis, or myocarditis.

Cl. Welchii and Gas Embolism

Q.—(a) What is the chemical nature of the gas produced in man by the gas-gangrene organisms (*Clostridium welchii*, etc.)? (b) Could the equivalent of "air embolism" be produced by this gas and lead to death from acute heart failure? I have in mind a case in which a clostridial infection followed a septic abortion, and death took place comparatively rapidly, with collapse, low blood pressure, and intense dyspnoea, clinically resembling pulmonary embolus. On opening the innominate veins at necropsy large bubbles of gas escaped.

A.—(a) Hydrogen and carbon dioxide in the proportion of about three parts to one. (b) No. Gas is found in considerable quantity only in tissues rich in fermentable carbohydrate—that is, muscle and liver. It is true that a small amount would be formed from blood sugar, and the accumulation of this after death might account for the appearance observed, but it could not conceivably accumulate during life in such volume as to cause fatal gas embolism. If embolism did occur in this case, is it not much more likely to have been due to the detachment of a thrombus?

Absorption of Dead Foetus

Q.—Can a dead foetus in utero (missed abortion) become absorbed and disappear with little external loss? Can such absorption be associated with toxic effects such as headaches, nausea, fainting, and leucocytosis?

A.—If the dead foetus is small, as in the first trimester, it is often absorbed and not found when the products of conception are expelled or removed. This is the case, for instance, in carneous moles. If by "foetus" the questioner means all the products of conception, the answer is still "yes." Even at term a placenta may be absorbed *in utero*, as has happened where a placenta accreta has been left *in situ* and a subsequent pregnancy has occurred. The absorption of a missed abortion may be accompanied by the signs and symptoms mentioned.

Persistent Sciatic Pain

Q.—A patient developed acute meningitis following cinchona hydrochloride injection, and this responded to treatment with sulphonamides. A month after his discharge from hospital he was readmitted because of left sciatic pain. This was increased by coughing, but there was no low back pain. The patient had a leucocytosis, but was afebrile, and there were neither motor nor sensory signs. Penicillin, 130,000 units in eight intrathecal injections, brought the white count to normal but had only a transitory effect on the pains. Is this a case of nerve-root compression due to inflammatory fibrosis? What treatment would you suggest, what investigation, and what is the prognosis?

A.—This is a problem case on which it would be impossible to give a dogmatic opinion without first making a full examination of the patient. There appear to be three possibilities. The first is that the sciatic pain is due to irritative neuritis resulting from the intrathecal infection; but if this was the case it might be expected that the symptoms would be bilateral rather than unilateral. The second possibility is that the condition is one of root pressure caused by a prolapsed intervertebral disk. Injury to a disk in the course of a difficult or ill-performed lumbar puncture might predispose to later prolapse. The third possibility is that the symptoms are due to some quite independent condition, such as spinal or pelvic neoplasm or sacro-iliac disease.

Before deciding on the best form of treatment it will be necessary to establish the diagnosis with greater certainty. It should be easy enough to dispose of the third possibility—the least likely one—after careful investigations, which should include pelvic examination; radiography of the hip-joints, sacro-iliac joints, and lumbar spine; cerebrospinal-fluid analysis, with particular reference to the protein level and bacteriology; and determination of the erythrocyte sedimentation rate. Assuming that extraneous conditions are thus excluded, it will then be necessary to decide between prolapsed intervertebral disk and irritative neuritis. The degree of the leucocytosis at

the time of readmission is not stated; but unless the white-cell count was significantly raised it need not necessarily be regarded as an indication of reinfection, particularly as there was no pyrexia. Because of the unilateral nature of the pain, and of the history of repeated lumbar puncture, disk prolapse is the more likely possibility; and if examination of the cerebrospinal fluid reveals no significant abnormality such a diagnosis should be made provisionally and conservative treatment instituted. Incidentally, treatment on very similar lines would be appropriate for a case of irritative neuritis. This should consist of: (1) application of a well-moulded plaster jacket from pubis to mid-thoracic level, applied with the patient standing; (2) rest in bed in the jacket for three to four weeks; (3) if improvement is occurring, ambulation and limited activity in the plaster is then permitted for a further six to eight weeks before removal of the jacket; (4) subsequently, if necessary, the patient may be fitted with a lumbo-sacral belt of strong design, to be worn for six months or more according to the clinical indications. Treatment on these lines has been shown to give excellent results even in severe cases of prolapsed intervertebral disk and, particularly in a case such as this, it would be wise to continue with conservative measures for a considerable period before considering any form of operative treatment.

NOTES AND COMMENTS

Threatened Abortion.—Mr. L. W. HEFFERMAN (Swansea) writes in an answer given in "Any Questions?" (Jan. 22, p. 163) I notice that the final opinion appears to be to discontinue the use of progesterone for threatened abortion. The following case may therefore be worthy of record. The patient was a woman, now age 30, who in 1940, as a primigravida, had a miscarriage at six months. Just prior to this occurrence she was in an air-raid shelter at the back of the house while there was some bombing. She became pregnant again in 1941, and, having decided to get away from the bombing area, she went to the outskirts of the town. She again had a miscarriage at six months, and on this occasion, in addition to being in a safe area, there was neither air-raid warning nor bombs. In 1942 she was pregnant for the third time and decided to seek medical advice. We put her on progesterone, and she duly gave birth to a full-time baby girl weighing 7 lb. 2 oz. (3.2 kg.). In 1944 she had a miscarriage at two months. In 1945 she again became pregnant and again sought medical advice. She was put on progesterone once more and again had a baby girl weighing 8 lb. 12 oz. (4 kg.). She is pregnant again (expected date of confinement May 16), and we are treating her with progesterone. She sought medical advice because she had had a slight loss. At the moment the foetus appears to be very vigorous.

In addition to this case I have personal records of twelve other cases, all of whom as primigravidae lost their first pregnancies. All the twelve subsequently in their second pregnancies were treated with progesterone. Eleven had full-time normal infants, but one had miscarriage for the second time in spite of progesterone. I have not seen her since, and in this case the Rh factor may be to blame. I notice that vitamin E was recommended, but I look upon this as more useful from a fertility point of view rather than for keeping the foetus *in situ* after the pregnancy has occurred.

Correction.—In the paper "Paludrine" (Proguanil) in Prophylaxis and Treatment of Malarial Infections Caused by a West African Strain of *P. falciparum*, by Sir Gordon Covell and others (Jan. 1, p. 88), a mistake occurred in describing under "Prophylactic Trials" how the patients were infected with malaria. The sentence should read: "The patients were infected once weekly over a period of 5 weeks, each subject under prophylaxis alternately being bitten by five to ten heavily infected mosquitoes one week and receiving the next week intravenous injection of a suspension of the salivary glands of one heavily infected mosquito by the technique described by Shu (1937)."

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: Altitol, Westcent, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the British Medical Journal and unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: Britmedads, Westcent, London. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, 11, BEDFORD SQUARE, LONDON, W.C.1. TELEGRAMS: Medisecra, Westcent, London.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY FEBRUARY 12 1949

THE SECRETARY REPORTS

THE SPENS APPROACH

There are two quite different groups of recommendations in the general practitioner Spens Report. The committee began by asking itself whether general practitioners as a body were receiving enough before the war. It had before it Professor Bradford Hill's estimate of the gross aggregate general practitioner income and his report on its spread among different practitioners.

The first, and not least important, conclusion of the committee was that the gross aggregate income was not enough. In effect, they said it was £3 million a year short of what it should have been. This conclusion stands quite apart from the Spens recommendations on how income should be spread among general practitioners, what percentage should receive one level and what percentage should receive another level of remuneration. While the difficulties of comprehending the Spens recommendations of the spread of income among general practitioners are very great even to those who have read the Report again and again, no such difficulty exists in understanding the Spens conclusion that general practitioners were underpaid before the war to the tune of £3 million a year. In fact, this conclusion enables us to calculate what the aggregate pool of general practitioner income should be to-day. In round figures general practitioners were receiving £28 million before the war. As this was £3 million short they should have been receiving £31 million. Spens says that that £31 million should be translated into terms of post-war money having regard to two things—the changed value of money and the increases received by other professions. In other words, the £31 million should receive proper betterment. But before making the calculation for betterment it is necessary to recall that at the time the £28 million was received by general practitioners the number of principals was 17,900. To-day it is over 20,000. Unless over 20,000 practitioners are to share a pool designed for 17,900, the pool must be adjusted for the additional number of practitioners sharing it. The adjustment is of the order of £3½ million. This brings us, on the basis of Spens, to £34½ million. Another adjustment is necessary because the number of people in England and Wales and Scotland is greater than it was in pre-war days. Another £1 million has to be added for this. We now reach £35½ million.

What should the betterment factor be? The Government first announced its figures of 20% addition to the net remuneration and 55% addition to the practice expenses element rather more than two years ago. At that time the figure which represented the increased cost of the middle-class budget, as calculated by an expert, was in the region of 45%. To-day the figure, as calculated by the same expert, is 85%. To put it at its lowest, if 20% was the right figure at the end of 1946 when the real figure was 45%, the right figure to-day is not less than 60%. Indeed, unless the 20% became something between 50% and 60%, general practitioners would have suffered a loss of real remuneration between the announcement of the Government's figure and its coming into operation. We could fairly claim that the figure should be somewhere between 160 and 185, taking pre-war as 100.

Size of Central Pool

The point I am trying to make is that, quite regardless of the mode of distribution, it is possible to negotiate the two adjustments which should be made in the size of the central pool to make sufficient money available for the remuneration of general practitioners. After all, unless the pool is of the right size the recommendations of Spens on its proper distribution can never be achieved.

Some people, remembering the difficulties imposed by the central-pool conception in Insurance Acts days, are wondering whether it would be wise to return to it. The difficulty about the old central pool was that it needed legislation to enlarge it. But this no longer holds. Bearing in mind that in the future the remuneration of a practitioner will need to be adjusted for the number of doctors who enter the Service as well as for the population and the betterment, there is a strong case for proceeding by stages, the first stage being to ensure that the aggregate pool is of the right size, the second being to secure its proper distribution.

Review of Hospital Staffs

Boards of guardians and regional hospital boards are now faced with two problems of unusual concern to the profession. The first is the decision which of the members of the hospital staffs they have inherited should be graded as specialists, and the second the allocation of duties to members of hospital staffs. On the first point the Ministry has made plain its views, which can be summarized in the following terms. Where a practitioner is engaged also in general practice, regard should be had to length and nature of experience and to the practitioner's standing as a consultant among his colleagues. The determination of status cannot depend solely on the possession of a postgraduate qualification but must take account of experience. Practice exclusively as a consultant or specialist cannot be employed as a criterion, since a number of practitioners engaged in other medical work may be qualified as specialists by experience or otherwise, and their services will be essential for the adequate staffing of the hospitals.

On the second point—the allocation of duties—the Ministry's view is that regard should be had both to the needs of the Service and the circumstances and preferences of the individual practitioner. It may be that a practitioner now working in two fields of medical practice may wish to confine himself to one, either as a whole-time or as a part-time officer. It may be that a whole-time officer may wish to be employed as a part-time officer in the Service. On this second point—the possibility of transferring to whole-time or part-time service—some doubts have been raised about the superannuation position. Would a practitioner making such a transfer lose in terms of superannuation? In general it may be said that the superannuation terms for the part-time officer are more favourable than those for the whole-time officer. In the former case the calculation of pension is based on 1½% for each year of service, whereas in the case of the latter it is based on 1%.

There is an important proviso: in the case of the part-time specialist who devotes the bulk of his time to the Service the Minister may direct that the pension shall be assessed on 80ths (i.e., 1¼% for each year). If this proviso should come into operation in the case of an individual the result is that his mode of calculating pension is the same as for full-time service, the amount of the pension depending on the average remuneration in the last three years' service. He would receive for twenty years' service 20/80ths of that average remuneration, while in cases where the proviso does not apply the corresponding pension would be 1¼% of the total remuneration over the twenty years. If a whole-time officer transfers to, say, nine sessions, those nine sessions being maintained until the end of his career, the amount of the difference is likely to be relatively small. To sum up, the change in the pension position will be relatively small provided the number of sessions is high and—this is a most important proviso—the rate of sessions is maintained until the retiring age.

National Health Service

THE NATIONAL FORMULARY

The new *National Formulary* has been published (see *Journal*, p. 278), but will not be put into use for some weeks, since time must be allowed for circulation to manufacturing chemists, retail pharmacists, and the issue by executive councils to doctors on their lists. Every practitioner giving general medical services may expect to receive a copy early in April.

On or about May 1 the *National War Formulary* will cease to be the official formulary and will be superseded by the *National Formulary*. Prescribers are asked to refrain until then from using the titles or abbreviated titles of the new *Formulary*.

DEPENDANTS OF FORCES PERSONNEL OPHTHALMIC SERVICES

The Minister of Health has decided that an appropriately qualified ophthalmologist in the armed Services may prescribe on Form O.S.C. 2 for the wives and families of Service personnel. He should first apply to the Central Professional Committee for inclusion in the central list of practitioners having the prescribed qualifications. When his application is accepted he may apply to the local Ophthalmic Services Committee of his area for the inclusion of his name on the committee's ophthalmic list. His application should be on Form O.S.C. 11, obtainable from the committee concerned.

No fee is payable by the executive council for the sight test, and therefore the Service ophthalmologist does not use Part 5 of Form O.S.C. 2. Otherwise the ordinary procedure applies and the patient must obtain an initial recommendation, which may be given by a Service medical officer. These arrangements do not preclude the dependants of Service personnel from using the Supplementary Ophthalmic Service.

INCORRECT INCOME TAX DEDUCTION

Some Government Departments and local authorities are said to be deducting income tax at source even where the medical practitioner's services are of a casual nature. This procedure is incorrect.

The Board of Inland Revenue gives the following opinion: "Income tax should not be deducted from the fees or salary paid by a public department to a medical practitioner whose main source of income consists in private practice, except in cases where instructions to deduct tax under P.A.Y.E. are received from the Chief Inspector of Taxes (Departmental Claims Branch). Normally such payments are assessed on the recipient under Schedule D of the Income Tax Act, 1918, and are consequently outside the scope of the P.A.Y.E. system. The appointment of a medical practitioner to a salaried part-time post should, however, be notified to the Departmental Claims Branch when it is made, and a return of the salary and fees paid to him in respect thereof in any income tax year should be sent to that office as soon as possible after April 5. Where fees are paid for attendance on individual patients otherwise than in virtue of a salaried appointment, there is no obligation on the paying department to make a return to the Departmental Claims Branch."

(There was a note on a similar case of incorrect deduction by a regional hospital board in the *Supplement* of Oct. 16, p. 143.)

TRAINING OF NURSES

The Women's Liberal Federation discusses nurses in its pamphlet *The Great Partnership*. It emphasizes the importance of human relationships in maintaining a happy and efficient nursing staff. The preliminary training course should last 18 months to two years, and, except for the first three months, should be carried out in hospital. It should cover the minimum of essential theory and emphasize the learning of practical nursing skills. Those who pass a practical, oral, and written test at the end of the course should be entitled to

registration as "Enrolled Nurse." The staffing of hospitals should not be entirely dependent on the work of student nurses; enrolled nurses and domestics should take over some of the work. An advanced course lasting two years after the basic training should be taken by all those wishing to rise in the profession. Another six months should be spent on specialization. No nurse should be appointed to a position of responsibility without the advanced certificate which would give her State registration.

HOSPITAL APPOINTMENTS FOR EX-SERVICE DOCTORS

The Ministry of Health scheme for the postgraduate education of medical officers released from the Forces provided hospital posts:

(a) for practitioners who were called up within a year or two of qualifying, and on release required a period of hospital experience before entering general practice. These are Class I posts; salary at the rate of £350 per annum, plus £100 per annum if non-resident; period of tenure six months.

(b) for practitioners who before being called up were being trained to become specialists or consultants and on release desired to continue their training. These are Class III posts; salary at the rate of £550 per annum, plus £100 per annum if non-resident; period of tenure six months renewable for further periods of six months as necessary.

In some cases practitioners who had not begun to specialize before joining the Forces, but desired to do so on release, were given an initial period in a Class I post and, if suitable for specialized training, transferred to posts in Class III.

The scheme will be continuing under the National Health Service, and the postgraduate deans and directors of the universities are carrying on the work they have done hitherto in connexion with it, in co-operation with hospital management committees and the boards of governors of teaching hospitals. In future, however, practitioners recruited, shortly after qualifying, for service starting after Dec. 31, 1948, will not be eligible for appointments under the scheme when released, while those whose recruitment is deferred up to the age of 30 and who have started specialist training will still be eligible for Class III appointments on release. These appointments will usually be their pre-Service appointments (or equivalent ones) and will be on normal hospital establishments, but if necessary supernumerary appointments may be created.

PRESCRIPTIONS FOR OUT-PATIENTS

Where a hospital or clinic in the Service has neither a dispensary of its own nor regular and convenient arrangements for dispensing out-patients' prescriptions at another hospital, prescriptions may be given to out-patients for dispensing without charge by any chemist providing pharmaceutical services under the N.H.S. Act. No charge will fall on the hospital's accounts. Prescriptions issued under these arrangements must be signed by a doctor and may relate only to drugs and appliances, not to foods or toilet preparations.

In order that the patient may get it dispensed without charge, the prescription must be made out on a special form which is being prepared, at the foot of which the name of the hospital should be stamped. The Ministry states that it is impossible at present to extend these arrangements to hospitals which have their own regular arrangements for dispensing.

MEDICAL PRACTICES ADVISORY BUREAU A BRANCH IN EDINBURGH

An appointments information service is now available at the Association's Scottish Office. Doctors seeking openings in general practice, or the introduction of locums, assistants, or partners, should address inquiries to the Medical Director, Medical Practices Advisory Bureau, 7, Drumsheugh Gardens, Edinburgh, 3.

AUSTRALIAN HEALTH SERVICE ACT

The Federal Parliament of Australia passed the National Health Service Act at the end of 1948. It is an enabling Act providing for a service whose general administration will be under the Director-General—a legally qualified medical practitioner of not less than 10 years' standing. The services to be provided include general medical or dental practitioner services, consultant and specialist services, ophthalmic services, maternal and child health services, aerial medical and dental services, diagnostic and therapeutic services, convalescent and after-care services, nursing services, and medical and dental services in universities, schools, and colleges. The Director-General may establish, maintain, and manage hospitals, laboratories, health centres, and clinics, and provide scholarships or training for university graduates and others who have completed courses of training. He may also

establish, maintain, or develop, or assist in the establishment, maintenance or development of, courses of training in nursing (including dental nursing), dental hygiene, radiography, radiation therapy, physiotherapy, biochemistry, dietetics and other matters related to medicine or dentistry;

undertake or develop, or assist in the undertaking or development of, measures (including research and epidemiological investigations) for the improvement of health (including maternal and child health) and for the prevention of disease;

encourage group practice by medical practitioners and dentists; and

disseminate information relating to health and the prevention of disease.

The estimated cost with full participation of practitioners of the medical part of the services in the first year is £A6,000,000. The annual cost of the dental service is estimated to be £A4,000,000 within a few years.

Medical Benefit Scheme

Speaking on the Second Reading of the Bill in the Senate on Nov. 24, 1948, Senator N. E. McKenna, Minister for Health and Social Service, said that the Government's proposals were to pay 50% of the fees charged by the doctor for services given the patient, and to pay this amount on behalf of the patient direct to the doctor in accordance with a prescribed schedule of fees chargeable by doctors who participated in the scheme. The scheme would be begun as soon as possible and be extended as rapidly as circumstances permitted to include the various classes of specialists on terms similar to those for general practitioners. It was thought that full-time salary would be appropriate payment for medical practitioners in remote country areas, for full-time specialists, such as pathologists and radiologists in hospitals, with sessional fees for other specialists, and salaried service for medical superintendents and a full-time staff at hospitals.

The details of the scheme will be laid down in regulations. Practitioners will be required to make available the records of their services to patients in order to obtain their remuneration.

Health Centres

Senator McKenna said that the Commonwealth proposed to establish a number of health centres in different areas. They would correspond in function to the surgeries of the larger medical partnerships of the present day, and would provide general practitioner service, specialist service, and diagnostic facilities. It was contemplated that they would be established on varying administrative staffing bases, so that there would be opportunities for observation and comparison for future guidance.

Compensation

The Act provides for the payment of compensation to a medical or dental practitioner who is in practice in or near a place where a hospital, health centre, or clinic is established in connexion with the Health Service; who undertakes to make his professional services available exclusively for the Health Service; and who has thereby suffered or will suffer loss arising from a diminution in the value of his practice.

Hospitals and Other Services

The following may be taken over for the purposes of the service: (a) any medical service or dental service; (b) the whole or part of any hospital, laboratory, health centre, or clinic; and (c) any property used in connexion with these. The Minister may arrange for, or undertake, the manufacture of medical and dental supplies, appliances, and equipment, including visual aids and hearing-aids.

Specialists

The Director-General may "compile and publish a list of medical practitioners or dentists recognized by him as being specialists in any field of medical science or dental science." For a person to be recognized as a specialist the Director-General must be satisfied that he works wholly or mainly in that field and is generally regarded by medical practitioners or dentists as having special skill and experience; or that he has special academic qualifications in that field and has recently held or holds a hospital or other appointment affording opportunities for acquiring or demonstrating special skill and experience in that field. For guidance the Director-General may consult any list compiled by the appropriate State authority or professional body. A person who wants his name to be included in the list must apply to the Director-General, who may refer the application to an Advisory Committee.

Conflict with Profession

The Federal Council of the B.M.A. considers that the Act is unacceptable to the profession. In the first place it would prefer the control of the service to be in the hands of a corporate body composed predominantly of medical men instead of under the Director-General of Health. It fears the encroachment of State control over all aspects of medical practice, particularly since the Act allows the Government to make regulations that would bring the whole medical profession under its complete control. At the Council's meeting in December, 1948, it held that no regulations under the Act should be promulgated unless they have first been approved by the controlling corporate body. The Council points out that the system by which a doctor claims his fees for the items of service rendered to patients necessitates a breach of his confidential relationship with those patients. Further, the public would strongly object to having such details inspected by Government officers. Practitioners would be unwilling to undertake the clerical work and liabilities involved in acting as the agent for the patient obtaining medical benefits. They would prefer the refund system by which the patient pays the whole fee to the doctor and claims a refund of half the fee from the Government. The Council refused to admit the right of the Government to fix a fee of which it paid only a part, and therefore demanded that a scale of benefits and not a fee should be laid down.

In reply to a request from the Minister that a joint committee of Government and Federal Council Representatives should be set up, the President, Sir Henry Newland, wrote: "The medical profession . . . would insist that payment by the refund system be included in the scheme. . . . The Federal Council agrees to the principle of a joint committee of representatives of the Government and the Council to consider certain details of the proposed scheme, but only when major matters of policy had been agreed to by both parties. It will be prepared to participate as a whole in a joint committee when such agreement has been reached."

In his reply the Minister said: "Your intimation that your Council 'insists' that the Government makes its contribution to the hundreds of thousands of individual patients per month instead of to a few thousand doctors as a condition precedent to its participation in a joint committee is a presumptuous prerequisite and is accepted by the Government as an express rejection of its proposal for the establishment of a joint committee. . . . I have to convey to you the decision of the Government that, within the limits of constitutional power, it will proceed to put its plans into operation."

After saying that members of the Government have declared that no measure for the control of the Health Service is likely

to prove effective unless the co-operation of the medical profession is obtained, a leading article in the *Medical Journal of Australia* of Feb. 5 continues: "The members of the medical profession cannot be expected to consent to take part in a service which, according to the expressly stated opinion of the Minister, has as its ultimate aim the abolition of private medical practice—in other words, the denial of the freedom of the individual. From the point of view of the public it is abundantly clear that the sick person is to be regimented as well as the doctor, and that he will be liable to a scrutiny which should not even be regarded as possible in what is held to be a democratic community."

A VISIT TO THE EAST AFRICAN BRANCHES

BY

E. GREY TURNER, M.C., M.A., M.R.C.S., L.R.C.P.

Assistant Secretary, B.M.A.

London Airport was soaked in rain and the Thames was over its banks as we crossed it in a B.O.A.C. York. The rain cleared over central France, and the navigating officer pointed out Mont Blanc standing high and clear 150 miles to the east. The Rhône was in flood: from its mouth a huge tongue of dirty brown water stretched out many miles into the deep-blue Mediterranean. Unfortunately there was cloud over Tunisia, but I recognized the salt lake behind Tunis, and Sousse and Monastir. We spent the night at Tripoli. Next morning we flew over Benghazi and Alamein. The Delta—green, fertile, intensively cultivated and densely populated—looked exactly like a huge infarct in the desert. Cairo airport showed signs of war—Egyptian fighters ready to take off, A.A. batteries manned, sentries with bayonets fixed. I had arranged to meet the Honorary Secretary of the Egypt Branch, Dr. W. H. Hamilton, and we had a short but enjoyable lunch together. This brief contact was the first of many reminders that the Association has thousands of loyal members scattered all over the world. The Egypt Branch is unique in that it is the only Branch in a completely foreign country.

At Khartum I was met by the Honorary Secretary of the Sudan Branch, Dr. H. M. Elliott, who drove me to the Kitchener School of Medicine, where I had the pleasure of attending a meeting of the Branch. At their request I gave a talk on the National Health Service. Throughout my tour all doctors showed intense interest in the National Health Service and in the affairs of the profession at home. The Sudan Branch holds monthly meetings, and appears to be full of vitality. It is not always appreciated that in many ways the Association plays an even more important role overseas than it does at home. In most places it is the only medical body, and in many—such as Dar-es-Salaam and Kampala—it is the only scientific or cultural society of any sort. For these reasons, apart from any others, the B.M.A. is greatly esteemed overseas. The *British Medical Journal* and the Association's other publications are keenly appreciated everywhere. Our overseas Branches play a vital part in the life of their communities.

On the third day we arrived over the green and undulant highlands of Kenya and crossed the Equator, at which point all passengers were formally enrolled into the Winged Order of Line Shooters. I spent the next six days there. In the course of my stay I met nearly all the many members of our profession in Nairobi, which includes a high proportion of private general practitioners and specialists as well as the Government medical officers; and also the Chief Secretary (who was Acting Governor), the Chief Justice, the Member for Health (Mr. C. E. Mortimer), and the Director of Medical Services, Dr. N. M. MacLennan. I spent a day in the Kiambu Native Reserve, where I had the good fortune to meet an African chief, Waruhiu, a man of very impressive intellectual and moral stature. I visited the Native Hospital, the Kiambu Hospital, the Mathari Mental Hospital, the pathological laboratory, and maternity and child-welfare clinics. In all of these, just as in all the other East African medical units which I was able to visit, a very high standard of clinical and educational work is achieved in spite of overcrowding, shortage of staff, and

unsuitable buildings. I was particularly impressed with the Mathari Mental Hospital, where Dr. J. C. Carothers has 400 patients of all races (in the whole of East Africa there is a large Asian population besides the African and European) under a minimum of restraint and in beautiful surroundings. The discharge rate is 75%, and the percentage of relapses within five years is low.

Population Problem

I attended a meeting of the Kenya Branch Council and addressed a full general meeting of the Branch. The Kenya Branch, and particularly my host, Dr. A. R. Paterson, are deeply concerned by the population problem in East Africa. Briefly, the problem is this: there is strong evidence that the native population of Kenya is increasing at a rapid rate (between 1% and 2% a year), while it is certain that the productivity of the land is declining fast owing to soil erosion, overcropping, and overgrazing. The combination of a rapidly expanding population and a rapidly dwindling food supply points clearly towards disaster. Dr. Paterson (who was once described by Julian Huxley as "like a very strong monsoon") is convinced that this threat overhangs all Africa south of the Sahara and (not unnaturally) that it overshadows all other questions. To my surprise, the population problem was scarcely mentioned in either Tanganyika or Uganda, but its existence in Kenya is visible even to the newly arrived visitor.

I know how dangerous it is to draw any conclusions from a brief visit, but flying across Kenya one can see many areas where vegetation is giving way to red desert, and one of my earliest impressions on landing was of the thinness of the Africans and their cattle. Of course a great number of factors, known and unknown, enter into this question, which is stated here only in barest outline. The agricultural and economic half of the problem is being energetically tackled by the Government. It is the much more difficult demographic half with which the Kenya Branch are concerned; and they consider very seriously that the whole subject of health and population in the African colonies should at once be investigated at the highest and most authoritative level—namely, by a Royal Commission.

On Jan. 12 I flew to Dar-es-Salaam, touching down *en route* at Tanga, where one of the medical officers stationed there met me to discuss a number of points. Tanganyika was extremely hot, far hotter than Kenya, where the weather had been like spring in England. My kind and thoughtful host was Dr. D. A. Skan, President of the Tanganyika Branch. Dr. Skan is the senior pathologist, and he showed me in his laboratory a German tablet commemorating the period when Robert Koch worked there on malaria. The Tanganyika Branch had arranged a full programme for my stay. I visited all the hospitals, met the medical profession of Dar and an up-country representative, and lunched at Government House with the Acting Governor. Dr. P. A. T. Sneath, the Director of Medical Services, very kindly entertained me to a large dinner-party at the Dar-es-Salaam Club.

Dissatisfaction in C.M.S.

Tanganyika is in many respects quite different from Kenya (as incidentally is Uganda), and the Tanganyika Branch is much different in character and outlook from the Kenya Branch. The Tanganyika Branch is composed almost entirely of Government members. It is no secret that the Colonial Medical Service is at present unpopular, and one of the principal objects of my tour was to investigate the causes of dissatisfaction with our members on the spot. One of the chief causes lies in the recruitment department of the Colonial Office. It is clear that in many cases incomplete or even inaccurate information is given to candidates about the work of a Colonial Medical Officer. Many men seem to have been recruited in the belief that their work would be purely clinical, and are aggrieved and frustrated when they discover their error. There is, of course, an immense and fascinating field of clinical work for the colonial medical officer, but he must also be prepared to occupy himself with a good deal of public health and social medicine, and with a certain amount of plain colonial administration—i.e., the government of backward peoples. There are plenty of doctors who would be attracted by a varied career of this sort.

Safe, effective bacteriostasis with 'SULFEX' in nasal and sinus infections

The intranasal use of 'Sulfex' ensures prolonged local bacteriostasis and prompt vasoconstriction. The microcrystalline ('Mickraform') sulphathiazole forms a fine, even 'frosting' over the nasal mucosa, and makes possible the maintenance of high local concentrations with the minimum of systemic absorption. The shrinking action of 'Paredrinex' renders the tissues more accessible to the sulphathiazole and promotes ventilation and drainage. 'Sulfex' is indicated in nasal and sinus infections — particularly those secondary to the common cold—and in sore throat. It is equally suitable for children and adults.

'Sulfex' is an aqueous suspension of microcrystalline ('Mickraform') sulphathiazole, 5%, in an isotonic solution of 'Paredrinex', 1% (pH 5.5 to 6.5). Issued in 1-oz. and 8-oz. bottles.

CASE HISTORY

M.R. Aged 40. Housewife. Varicose ulcer with severe eczema right leg. (Fig. 1).

TREATMENT

August 9th, 1946.—Ulcer and surrounding skin cleaned with cod liver oil. Strips of Jelonet were applied to cover the ulcer and the eczematous area, with a pad of cotton-wool over the ulcer only. The whole leg was bandaged with Ichthopaste and then with Elastocrepe. (Fig. 2).

August 23rd, 1946.—Ichthopaste and Elastocrepe bandaging repeated.

Sept. 13th, 1946.—The œdema was reduced and the leg much less painful. Calamine lotion was

Fig. 2

VARICOSE ULCER WITH ECZEMA

Healed beneath Pressure Bandaging

applied over the whole area with a pad of cotton-wool and felt over the ulcer, and the leg again bandaged with Elastocrepe.

October 4th, 1946.—Calamine lotion, pad of cotton-wool and Elastocrepe repeated.

October 11th, 1946.—Repeated.

November 1st, 1946.—Condition healed. (Fig. 3). The patient was instructed to continue application herself of calamine lotion and Elastocrepe.

COMMENT. In this case the eczema was more troublesome than the ulcer. Both responded to the soothing effect of Ichthopaste and the firm pressure of Elastocrepe. Details and illustrations above are of an actual case. T. J. Smith & Nephew, Ltd., Manufacturers of Jelonet, Ichthopaste and Elastocrepe are privileged to publish this instance, typical of many, in which their products have been used with success, in the belief that such authentic records will be of general interest.

and if the Colonial Office stated the full facts plainly they would obtain recruits who would know what to expect and would enjoy it.

Another cause of low spirits in the Colonial Medical Service is the fault so commonly found in all large branches of Government service—bad man-management. The two essentials of man-management are personal interest and diffusion of information. A good leader of men, whether a general in command of an army, or the D.M.S. of a colony, or the S.M.O. of a province, will—at whatever cost to his other work—make frequent personal contacts with his subordinates and make them feel that he takes a personal interest in their work. He will also keep them fully informed of policy and developments at higher levels. Colonial medical officers are required to submit regular reports to their superiors; but I found no evidence of any flow of information in the opposite direction. As a result a number of medical officers seemed to be groping in the dark, without any clear idea of what purpose they were expected to achieve. Part of the blame for this lies also upon the Colonial Governments, who do not always appear to have formulated any clear medical policy. If the medical staff are to know what is expected of them, it is essential that the Government should sit down with its advisers and work out what purposes it proposes to achieve with the medical resources at its disposal.

There are other causes of dissatisfaction. Colonial medical officers are required to carry a heavy burden of secretarial and clerical work, much of which is purely financial accounting and book-keeping. I found a ready realization at the secretariats that this was entirely inappropriate work for doctors—one governor remarked that doctors are notoriously bad at figures anyhow—and in all three territories attempts are being made to recruit the non-medical staff necessary to take on this work. A more serious complaint, frequently heard, is that medical officers are judged more by their reports and returns than by their medical work. A D.M.S. pointed out that a good man is good at both, but it is unfair to a man to assume that he is bad at both because he is bad at one. The only fair method of assessment is by personal knowledge of the man and his work.

Then there are salaries, with which is bound up the vexed question of private practice. There is fairly general agreement that the Secretary of State's decision three years ago to abolish private practice in the Colonial Medical Service is simply not practicable in many stations. The difficulty is to devise a scheme of private practice which avoids the undesirable features of the old system. As regards salaries, there is no doubt that the remuneration of colonial medical officers, even after the recent revisions, lags appreciably behind the Spens standards. There are of course advantages in colonial life, though these must be weighed against heavy disadvantages. There is no doubt, too, that the Colonial Medical Service offers a magnificent field of clinical work and a fine opportunity to do a grand job for humanity. All these factors must be taken into account, and the East African Branches were deeply impressed by the exhaustive review which the Colonies Committee has recently completed of the terms of service in the Colonial Medical Service. Clearly the terms will require considerable improvement if they are to conform with Spens.

The last territory to be visited was Uganda. I flew from Dar-es-Salaam via Nairobi, where I spent a pleasant day with Dr. and Mrs. A. McK. Fleming, and Kisumu, where I had a short meeting with four medical officers stationed in the area. In Uganda, as in the rest of the tour, the most complete and admirable programme had been arranged for me by the Branch secretary, Dr. J. N. P. Davies, to whom the North Persian Forces Memorial Medal has just been awarded for his work on tropical diseases. I had the privilege and pleasure of visiting Sir Albert Cook at his beautiful home. Sir Albert, who has been fifty-two years in Uganda, founded the East African Branches and is the doyen of the profession in East Africa. I also met the Director of Medical Services, Dr. T. A. Austin, and the Governor, Sir John Hall, and lunched afterwards at Government House. I met Lieutenant-General Daubenton, of the Netherlands Army Medical Service, now WHO representative in Addis Ababa. He thinks highly of the medical services in our East African colonies. To our great pleasure General

Daubenton was able to attend the farewell dinner at the Imperial Hotel on the last night of my tour.

I addressed two meetings of the Uganda Branch and a meeting of the African Assistant Medical Officers. The Asian practitioners kindly entertained me to a large tea-party. The presence of three races in East Africa inevitably gives rise to complicated economic and political questions, and these have their reflection in the world of medicine.

I visited a number of hospitals, including Masaka, which is 84 miles up country, and Entebbe, where Dr. Fairfull Smith (of Glasgow) informed me cheerfully that medical practice in Darkest Africa is far preferable to practice in the Gorbals. The Mpigi dispensary comprises a busy out-patient department and three wards, all under the efficient charge of an African medical assistant (i.e., nursing orderly) with trained African female nurses to help him. This is rather larger than most of the up-country native dispensaries which I saw in East Africa. I visited a biggish hospital run by an Indian doctor for the employees of a 15,000-acre sugar estate. At all these institutions good work is being done, often under trying conditions. At Jinja I did not see the hospital, but enjoyed a long talk with five up-country medical officers and an R.A.M.C. officer attached to the King's African Rifles.

Makerere Experiment

Kampala is well equipped with hospitals, and is in some sense the medical centre of East Africa. Dr. A. A. Battson kindly conducted me round his attractive European Hospital. I spent an afternoon at Mengo, the pioneer hospital of the Church Missionary Society, nestling close to stately Namirembe Cathedral. Dr. R. T. S. Goodchild took me round and gave me an insight into the magnificent curative and educational work which the missions are doing and have done for so long. In the library at Mengo are kept all Sir Albert Cook's case reports since 1897. Mulago is the famous Government hospital, whose 1,000 beds make it the biggest in East Africa. It provides the clinical teaching for the medical school of Makerere College. The creation of a centre of university teaching for Africans is an ambitious project, and in the course of my tour I heard some criticisms of the Makerere experiment. All over East Africa I met medical diplomats of Makerere, and they impressed me very favourably.

But there are those who think that Makerere aims too high, and that it would have been wiser to move with less haste and to have concentrated at first upon a technical high school rather than a university; and in Uganda there are some who remark rather bitterly that all the medical resources of the territory are poured into Makerere and Mulago to the detriment of the remainder. There is some foundation for these criticisms; but I am inclined to agree with Dr. Eric Holmes, Makerere's distinguished professor of physiology, that the Makerere experiment, in spite of all its obvious dangers and difficulties, can and must succeed.

Thus ended my tour of the East African Branches. The overseas members were athirst for first-hand information about many things at home, and they were desperately eager to discuss their great and peculiar problems on the spot with a representative from Headquarters. The Association is a powerful Imperial link, embracing all territories and all races. I received the greatest hospitality and kindness from all members, and I was struck with the loyalty and affection of our overseas Branches towards the parent body. More than all this, however, I was enormously impressed by the devoted and skilful work which is being done, often under immense difficulties, by the medical profession in the colonies, whether in Government service, the missions, or in private practice.

The Ministry of Health states that some National Health Service doctors are continuing to prescribe on Form E.C.10 appliances which are not included in the Third Schedule (*Supplement*, Nov. 13, 1948, p. 172). Only appliances named in the Third Schedule may be ordered on Form E.C.10, and chemists are not authorized to dispense prescriptions for appliances not named in that list. Medical and surgical appliances not included in the Third Schedule may be supplied through the hospital service where considered necessary by a specialist at a hospital in the Service.

STANDING ADVISORY COMMITTEES

The following are the members of the Standing Advisory Committees set up by the Minister of Health other than the Medical Advisory Committee, whose composition was published in the Supplement of Feb. 5 (p. 58).

Standing Dental Advisory Committee

(a) *Members Appointed by the Minister after Consultation with the Central Health Services Council.*—Mr. F. J. BALLARD, dental practitioner; member of N.W. Metropolitan R.H.B. and University College Hospital and Eastman Dental Clinic Boards of Governors (until March 31, 1952). Mr. J. LAUER, dental practitioner; member of Dental Estimates Board (until March 31, 1950). Dr. H. T. ROPER-HALL, dental practitioner (until March 31, 1951).

(b) *Members Appointed by the Minister after Consultation with Representative Organizations.*—Mr. L. C. ATKINS, dental practitioner (until March 31, 1953). Professor R. V. BRADLAW (invitation to serve not yet accepted), Dean of Durham University Dental School; member of Newcastle Board of Governors (until March 31, 1953). Mr. W. K. FRY, dental surgeon; member of S.E. Metropolitan R.H.B. and Guy's Hospital and Eastman Dental Clinic Boards of Governors (until March 31, 1953). Mr. T. HINDLE, dental practitioner (until March 31, 1952). Professor H. F. HUMPHREYS, professor of dental surgery, Birmingham University; member of Birmingham R.H.B. and Board of Governors (until March 31, 1951). Professor W. C. W. NIXON, obstetrician, University College Hospital (until March 31, 1951). Mr. J. F. PILBEAM, senior dental officer, Middlesex County Council (until March 31, 1951). Mr. J. A. T. ROWLETT, dental practitioner (until March 31, 1953). Professor M. A. RUSHTON, professor, Guy's Hospital Dental School (until March 31, 1952). Mr. T. G. WARD, dental practitioner; dental surgeon, Queen Victoria Hospital, Grinstead (until March 31, 1951). Dr. A. G. WATKINS, paediatrician; member of Cardiff Board of Governors (until March 31, 1952). Professor F. C. WILKINSON, professor of dental surgery, Manchester University; member of Manchester Board of Governors (until March 31, 1952). *Secretary:* Miss J. E. CHAPPLE (Victoria 8540, extension 70).

Standing Pharmaceutical Advisory Committee

(a) *Members Appointed by the Minister after Consultation with the Central Health Services Council.*—Mr. R. H. HENRIKSEN, chief pharmacist, Dulwich Hospital (until March 31, 1951). Alderman W. J. TRISTRAM, pharmacist; member of Liverpool Executive Council (until March 31, 1952).

(b) *Members Appointed by the Minister after Consultation with Representative Organizations.*—Professor H. BERRY, professor of pharmaceuticals (until March 31, 1953). Mr. J. O. DAVIDSON, pharmacist (until March 31, 1951). Mr. P. DOBSON, pharmaceutical chemist (until March 31, 1951). Dr. P. J. HIBBONS, general practitioner; member of Liverpool Executive Council (until March 31, 1952). Mr. J. GILMOUR, pharmacist (until March 31, 1951). Dr. C. H. HAMPSHIRE, secretary, British Pharmacopoeia Commission (until March 31, 1953). Mr. J. C. HANBURY, manufacturing chemist (until March 31, 1951). Mr. J. B. HOUGH, pharmacist, Royal Gwent Hospital (until March 31, 1952). Mr. H. N. LINSTED, secretary, Pharmaceutical Society of Great Britain (until March 31, 1953). Mr. G. A. MALLINSON, secretary, National Pharmaceutical Union (until March 31, 1952). Mr. D. E. SPARSHOTT, pharmacist (until March 31, 1952). Professor E. J. WAYNE, professor of pharmacology; member of Sheffield R.H.B. and Board of Governors (until March 31, 1953). *Secretary:* Mr. F. F. MARCHBANK (Victoria 8540, extension 353).

Standing Ophthalmic Advisory Committee

(a) *Members Appointed by the Minister after Consultation with the Central Health Services Council.*—Dr. Janet AITKEN, physician (until March 31, 1950). Sir Herbert Lightfoot EASON, President of the General Medical Council (while President of

(b) *Members Appointed by the Minister after Consultation with Representative Organizations.*—Mr. G. W. BLACK, ophthalmic surgeon; member of Leeds R.H.B. (until March 31, 1953). Dr. Macdonald CRITCHLEY, physician and neurologist (until March 31, 1952). Mr. O. M. DUTHIE, ophthalmic surgeon; member of Manchester Board of Governors (until March 31, 1951). Mr. G. H. GILES, ophthalmic optician and lecturer (until March 31, 1952). Mr. R. A. GREEVES, ophthalmic surgeon (until March 31, 1951). Mr. J. R. HOWARD, dispensing optician (until March 31, 1953). Mr. D. H. LEWIS, ophthalmic optician and lecturer (until March 31, 1953). Mr. O. G. MORGAN, ophthalmic surgeon (until March 31, 1952). Mr. A. E. TURVILLE, ophthalmic optician (until March 31, 1952). Mr. S. M. WELLS, ophthalmic optician (until March 31, 1951). Dr. O. WILLIAMS, general practitioner (until March 31, 1953). Mr. F. M. WISEMAN, manufacturing optician (until March 31, 1951). *Secretary:* Mr. S. G. GAME (Victoria 8540, extension 328).

Standing Nursing Advisory Committee

(a) *Members Appointed by the Minister after Consultation with the Central Health Services Council.*—Alderman A. F. BRADBEER, member of Birmingham R.H.B., Board of Governors, City Council and Executive Council (until March 31, 1950). Mr. F. J. CABLE, superintendent, Manchester Royal Infirmary (until March 31, 1952). Miss N. B. DEANE, matron, Bristol Maternity Hospital (until March 31, 1951). Sir Herbert Lightfoot EASON, President of the General Medical Council (while President of G.M.C.). Mr. S. C. FRYERS, house governor and secretary, Leeds General Infirmary; member of Leeds R.H.B. (until March 31, 1950). The Hon. A. J. P. HOWARD, chairman of St. Thomas's Hospital Board of Governors (until March 31, 1950). Sir Wynne Cemlyn JONES, member of Anglesey County Council and Executive Council (until March 31, 1951). Miss E. J. MERRY, education officer, Queen's Institute (until March 31, 1952). Miss M. E. G. MILNE, matron, St. Mary's Hospital (until March 31, 1950).

(b) *Members Appointed by the Minister after Consultation with Representative Organizations.*—Miss C. H. ALEXANDER, matron, London Hospital (until March 31, 1952). Miss C. F. S. BELL, matron, Leicester Royal Infirmary (until March 31, 1951). Dr. C. Fraser BROCKINGTON, county medical officer of health, West Riding (until March 31, 1953). Mr. E. DAWSON, chief male nurse, St. Ebba's Hospital, Epsom (until March 31, 1953). Miss M. M. EDWARDS, secretary, Nursing Recruitment Committee of King Edward's Hospital Fund (until March 31, 1952). Miss L. I. GALE, ward sister, Liverpool Children's Hospital (until March 31, 1953). Miss F. G. GOODALL, general secretary, Royal College of Nursing (until March 31, 1952). Miss E. M. HILLIER, matron, Crumpsall Hospital, Manchester (until March 31, 1951). Mrs. G. C. JONES, assistant nurse, Stapleton Hospital, Bristol (until March 31, 1951). Miss C. M. PAMK, ward sister, St. Bartholomew's Hospital (until March 31, 1951). Miss K. M. ROE, public health nurse, London County Council (until March 31, 1952). Miss A. E. A. SQUIBBS, sister tutor, Leeds Infirmary (until March 31, 1952). Miss J. E. THOMAS, matron, North Wales Sanatorium (until March 31, 1951). Miss B. J. WALL, matron, Barming Heath Hospital (until March 31, 1953). *Secretary:* Miss P. M. MUSGROVE (Whitehall 4300, extension 722).

Standing Maternity and Midwifery Advisory Committee

(a) *Members Appointed by the Minister after Consultation with the Central Health Services Council.*—Dr. Janet AITKEN, physician (until March 31, 1950). Dr. Aleck W. BOURNE, obstetrician and gynaecologist (until March 31, 1950). Miss N. B. DEANE, matron, Bristol Maternity Hospital (until March 31, 1951). Sir William GILLIATT, President of the Royal College of Obstetricians and Gynaecologists (while President). Dr. W. V. HOWELLS, general practitioner; member of Swansea Executive Council (until March 31, 1950). Miss E. J. MERRY, education officer, Queen's Institute (until March 31, 1952). Miss M. E. G. MILNE, matron, St. Mary's Hospital (until March 31, 1950). Professor J. C. SPENCE, paediatrician; member of Newcastle Board of Governors (until March 31, 1952). Mrs. D. THURTELL, member of London County Council and Shoreditch Borough Council (until March 31, 1950). Dr. C. W. WALKER,

general practitioner; member of Cambridge Executive Council (until March 31, 1950). Alderman W. E. YORKE, Lord Mayor of Sheffield; member of Sheffield R.H.B. (until March 31, 1951).

(b) *Members Appointed by the Minister after Consultation with Representative Organizations.*—Miss M. N. FENSOM, educational supervisor, Central Midwives' Board (until March 31, 1952). Miss E. F. GORE, supervisor of midwives, London County Council (until March 31, 1953). Miss D. M. HAYWARD, superintendent health visitor, Mitchenam Borough Council (until March 31, 1952). Dr. I. McI. MACKINTOSH, senior assistant medical officer (maternity and child welfare), City of Birmingham (until March 31, 1953). Mrs. F. R. MITCHELL, general secretary, Royal College of Midwives (until March 31, 1953). Miss M. O'CONNOR, member of Isle of Wight County Council and Executive Council (until March 31, 1953). Mr. E. W. SCORER, member of Sheffield R.H.B. (until March 31, 1951). Miss A. E. STEWARD, midwifery sister, Colchester Maternity Hospital (until March 31, 1952). Mr. A. WALKER, chairman, Central Midwives' Board (until March 31, 1951). Miss M. WILLIAMS, matron, Queen Charlotte's Hospital (until March 31, 1951). *Secretary:* Mr. E. HALLIDAY (Whitehall 4300, extension 178).

Standing Mental Health Advisory Committee

(a) *Members Appointed by the Minister after Consultation with the Central Health Services Council.*—Mr. C. F. COMER, general secretary, Confederation of Health Service Employees (until March 31, 1952). Sir Allen DALEY, chairman of the Council of the Society of Medical Officers of Health (while chairman of that Society). Professor A. J. LEWIS, psychiatrist; member of Bethlem and Maudsley Hospital Board of Governors (until March 31, 1952). Dr. W. G. MASEFIELD, psychiatrist; member of S.E. Metropolitan R.H.B. and Bethlem and Maudsley Hospital Board of Governors (until March 31, 1951). Sir Cecil OAKES, member of East Anglian R.H.B. (until March 31, 1951).

(b) *Members Appointed by the Minister after Consultation with Representative Organizations.*—Mr. C. BARTLETT, male nurse (until March 31, 1951). Dr. E. J. M. BOWLEY, child psychiatrist (until March 31, 1951). Dr. W. RUSSELL BRAIN, physician and neurologist; member of London and National Hospitals Board of Governors (until March 31, 1952). Dr. N. H. M. BURKE, medical superintendent, Cell Barnes Mental Deficiency Colony (until March 31, 1952). Dr. Desmond CURRAN, physician and psychiatrist; member of S.W. Metropolitan R.H.B. (until March 31, 1953). Dr. W. S. MACDONALD, general practitioner; member of Leeds R.H.B. (until March 31, 1953). Mrs. K. F. McDUGALL, psychiatric social worker (until March 31, 1951). Alderman M. PAYNE, member of Glamorgan County Council; chairman of Glamorgan Mental Hospital Management Committee (until March 31, 1951). Dr. J. R. REES, psychiatrist; member of N.W. Metropolitan R.H.B. (until March 31, 1953). Dr. J. I. RUSSELL, medical superintendent of North Riding Mental Hospital; member of Leeds R.H.B. (until March 31, 1952). Mr. P. E. VERNON, psychologist (until March 31, 1952). Miss B. J. WALL, matron, Barming Heath Hospital (until March 31, 1953). *Secretary:* Mr. H. J. CLARKE. (Kensington 3456, extension 5).

Standing Tuberculosis Advisory Committee

(a) *Members Appointed by the Minister after Consultation with the Central Health Services Council.*—Sir Wynne Cemyln JONES, member of Anglesey County Council and Executive Council (until March 31, 1951). Professor Sir Harry PLATT, orthopaedic surgeon; member of Manchester R.H.B. and Board of Governors (until March 31, 1951).

(b) *Members Appointed by the Minister after Consultation with Representative Organizations.*—Major L. E. BURY, member of Birmingham R.H.B. and Salop County Council (until March 31, 1953). Sir Brunel COHEN, chairman of Ministry of Labour Disabled Persons Advisory Council; member of St. Thomas's Hospital Board of Governors (until March 31, 1952). Miss M. S. COLTART, almoner, Brompton Hospital (until March 31, 1951). Dr. P. W. EDWARDS, medical superintendent, Cheshire Joint Sanatorium (until March 31, 1953). Dr. F. HALL, county medical officer of health, Lancashire

(until March 31, 1951). Dr. P. M. D'Arcy HART, Director of Tuberculosis Research, Medical Research Council (until March 31, 1952). Dr. F. R. G. HEAF, senior medical officer of health to London County Council; member of Board of Governors, Hospitals for Diseases of the Chest (until March 31, 1953). Dr. Peter KERLEY, radiologist (until March 31, 1952). Miss D. LAMBERT, health visitor (until March 31, 1952). Dr. Wilfrid SHELTON, paediatrician; member of King's College Hospital and Hospital for Sick Children Boards of Governors (until March 31, 1951). Miss A. R. SPALL, matron, Clare Hall Sanatorium (until March 31, 1953). Mr. C. P. THOMAS, surgeon; member of Board of Governors, Hospitals for Diseases of the Chest (until March 31, 1953). Sir Robert A. YOUNG, chairman of Board of Governors, Hospitals for Diseases of the Chest (until March 31, 1951). *Secretary:* Mr. H. R. HARTWELL (Whitehall 4300, extension 134).

Standing Cancer and Radiotherapy Advisory Committee

(a) *Members Appointed by the Minister after Consultation with the Central Health Services Council.*—Professor W. G. BARNARD, pathologist; member of St. Thomas's Hospital Board of Governors (until March 31, 1950). Sir Ernest ROCK CARLING, surgeon (until March 31, 1952). Professor Sir Henry COHEN, physician; member of Liverpool R.H.B. and Board of Governors (until March 31, 1952). Mr. S. C. FRYERS, house governor and secretary of Leeds General Infirmary; member of Leeds R.H.B. (until March 31, 1950). Dr. W. V. HOWELLS, general practitioner; member of Swansea Executive Council (until March 31, 1950). Dr. H. JOULES, physician and medical director; member of N.W. Metropolitan R.H.B. and Hammer-smith, etc., Board of Governors (until March 31, 1951).

(b) *Members Appointed by the Minister after Consultation with Representative Organizations.*—Dr. H. E. A. BOLDEO, physician; member of N.W. Metropolitan R.H.B. and Middlesex Hospital Board of Governors (until March 31, 1951). Dr. E. C. DODDS, biochemist (until March 31, 1952). Mr. E. FINCH, surgeon; member of Sheffield R.H.B. (until March 31, 1952). Mr. K. I. JULIAN, chairman of S.E. Metropolitan R.H.B.; member of Guy's Hospital Board of Governors (until March 31, 1952). Professor Hilda N. LLOYD, gynaecologist; member of Birmingham Board of Governors (until March 31, 1953). Professor W. V. MAYNEORD, physicist; member of Royal Cancer Hospital Board of Governors (until March 31, 1953). Professor J. S. MITCHELL, radiologist (until March 31, 1952). Mr. V. E. NEGUS, laryngologist (until March 31, 1952). Mr. J. R. K. PATERSON, radiologist (until March 31, 1953). Mr. J. A. STALLWORTHY, gynaecologist; member of Oxford R.H.B. (until March 31, 1951). Dr. M. J. STEWART, pathologist; member of Leeds R.H.B. and Board of Governors (until March 31, 1953). Mr. C. J. L. THURGAR, radiologist (until March 31, 1951). Professor R. M. WALKER, surgeon; member of South Western R.H.B. (until March 31, 1951). Professor B. W. WINDEYER, radiologist; member of Middlesex Hospital Board of Governors (until March 31, 1951). *Secretary:* Mr. R. GEDLING (Whitehall 4300, extension 253).

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), WallSEND.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

Local health authorities may have arrangements for the loan of sick-room equipment to patients being nursed at home—such articles as bedpans, urinals, mackintosh sheeting, feeding-cups, air rings, and bed cradles—and possibly larger items such as water-beds, bed-rests, or commodes may be available in this way, usually through the local home nursing services. For expectant mothers confined at home, local health authorities supply maternity outfits—usually through the welfare centre or district midwife.

HEARD AT HEADQUARTERS

A Changing Council

The proposals for reforming the methods of election to the Council are deferred to permit a study of the map of the new constituencies. Briefly, the proposals would have the effect of making the Council more like a house of representatives and diminishing the senate element. Some people have suggested that continuity of membership should be better provided for. New blood is let in liberally every year, and the average length of service on the Council is short. Out of the 64 members who were on the Council eleven or twelve years ago, only seven are on the present Council. This seems a very small number, although it does include some of those who then as now were most prominent in Association work. Of the 14 present chairmen of standing committees only three were members of Council at that time.

The New Formulary

During the last two years a joint committee has been hard at work devising a standard prescribers' formulary. The committee consists of representatives of the British Medical Association, the Pharmaceutical Society, the Royal Colleges, the Ministry of Health, and the Service departments. The idea has been to bring out a pocket volume which will be of real use to the busy doctor and will include a section for children's medicines, with preparations, especially linctuses and mixtures in a palatable form. The new *Formulary* has now come from the printers, and it is expected to be generally available in the spring. The Association and the Pharmaceutical Society are bearing the cost of publication, and the Ministry has undertaken to purchase bulk supplies for distribution through local executive councils to practitioners, dentists, and pharmacists on the lists of those bodies. It should also be popular in hospitals.

A Forensic Medicine Prize

Under the will of a well-known member of the Association, the late Col. C. H. Milburn, of Harrogate, the British Medical Association and the Medical School of the University of Durham are residual legatees subject to the payment of certain annuities and a life interest. Money is bequeathed to the Association for the purpose of founding a prize or prizes for essays on the subject of medical jurisprudence and forensic medicine. No definite information can be given about the amount likely to be received for this purpose, but it is said to be substantial.

Recruiting Medical Boards

The Pulheems system of classification, which was the subject of an article in the *Journal* recently, was said to call for a considerable reduction in the number of candidates who can be examined by National Service Medical Boards in the course of a 2½-hours session. The Ministry of Labour has stated that the Boards are expected to examine 20 men or 15 women at such a sitting. These numbers were temporarily reduced while the Boards were gaining experience of the new procedure, but it now appears that they can be examined without undue pressure during the prescribed time. This has been confirmed by the Gateshead Division, which brought forward a motion on the subject at the last Annual Representative Meeting. The Council of the Association, in view of these assurances, has agreed that unless further complaints are received no action shall be taken to obtain a reduction in the number of candidates per session.

Like the House of Commons

Some of the proposals in the memorandum by the Winchester Division on the organization of the Association are directed to the reform of the Representative Meeting. Among other things Winchester wants the Representative Body to be reduced to members, and it also suggests that the hall in which it meets should have its seating arranged like that in the House of Commons. The Council would then occupy the "Government" benches, and unofficial speakers would speak from their

places among their groups, so that, says Winchester, they would be less at a disadvantage than now. We doubt whether there is at present any particular disadvantage to an "opposition" speaker in having to come to the rostrum, even though he be deprived of the physical contiguity of his friends. Speech from the rostrum is usual in other parliaments. The special arrangement in the House of Commons, and the House of Lords, too, was due to the two-party system, which has no place in the Association.

Air Trips for N.H.S. Patients?

The altitude treatment of pertussis is said to give good results, but it is expensive. We have heard of parents paying five guineas to charter a plane for an altitude flight, and larger sums than that have been paid to charter-aircraft firms. If altitude treatment is of proved value it must presumably be included among the treatments which patients are entitled to expect from the State. A correspondent inquires whether arrangements may be made with charter-aircraft firms to carry out this form of treatment, the cost to be reimbursed by the Ministry of Health or the local executive council. It is not a question we can answer. The Ministry must give a ruling.

Questions Answered

Retirement for Health Reasons

Q.—*I may have to give up general practice for health reasons. I am in the N.H.S., aged 34, and in partnership. Am I entitled to compensation on retirement? Can I take up another branch of medicine? Does the practice as a whole get compensation, or do I get my share of the compensation only if my partner continues in practice?*

A.—Compensation is payable on "retirement from practice as a medical practitioner providing general medical services under Part IV of the Act, or under Part IV of the National Health Service (Scotland) Act, 1947" (Medical Practices Compensation Regulations, 1948). Payment does not affect the right of the practitioner to undertake medical work in other fields of practice. The practice as a whole is assessed for compensation, but each partner will receive an amount in proportion to the share of the goodwill he held on the appointed day, subject to any adjustment to meet provisions of the partnership agreement as recommended by the Legal Committee on Partnerships.

Training after Demobilization

Q.—*I am due for demobilization in a few weeks. I am a graded medical specialist in the Army, and I am eager to become a civilian specialist. Is there a scheme whereby prospective civilian medical specialists can receive a period of training with financial remuneration after demobilization from the Services?*

A.—Yes. You should apply for particulars to the Director, British Postgraduate Medical Federation Central Office, 2, Gordon Square, London, W.C.1.

Payment for Anaesthetics

Q.—*(1) I several times obtained the assistance of a practitioner to administer an anaesthetic while I performed a minor operation on a patient on my State list at my surgery or at the patient's home. How should payment for the doctor giving the anaesthetic be obtained?*

(2) A patient on my State list elected to have an operation performed privately by a specialist in a nursing-home, for which I gave the anaesthetic. Can I obtain payment for this service?

A.—*(1)* The practitioner administering an anaesthetic should submit a claim for an anaesthetic fee to the local executive council. The B.M.A. is at present discussing the question of anaesthetists' fees with the Ministry.

(2) The practitioner is not entitled to charge a fee to a patient on his public list in respect of an anaesthetic for an operation carried out by a specialist in a private nursing-home, unless the anaesthetist holds an appointment at a hospital providing specialist services under the Act.

Correspondence

Genuine Hardship

SIR.—There seems to be a considerable amount of discontent amongst the profession as a whole, and it is difficult to decide how many of the complaints are really genuine. In my opinion it is time there was a little more honesty about the general practitioner's approach to the whole problem and time that the claims of those who have really suffered hardship since the inception of the N.H.S. were pressed more strenuously to the exclusion of frivolous complaints—which in some cases have become almost a habit or an attitude of mind in recent years.

As senior partner in a partnership of four and chairman of the Herts Local Medical Committee I am convinced that the only genuine hardship in the case of the practitioner with a list of over 2,500, or the partner in an active firm with a solid list, is that the items of service demanded by the patients have increased since July 5. There is unlikely to be much, if any, financial hardship, but the strain is so great that the employment of an assistant or the addition of an extra partner is essential for the maintenance of health. This will mean a diminution in income, and this again in a partnership will affect chiefly the junior partners. There is still in addition considerable disquiet about the future of partnership practice, and this is proving a particular hardship to the young assistant, whose future is indefinable at present. As many of those assistants have given several years in the Services and have family claims, the hardship is particularly pronounced. This can only be relieved by an increase in the capitation fee to permit of the employment of an assistant at a decent salary or a more satisfactory clarification of the partnership problem to permit of additions to a firm and not necessarily replacements of retiring or deceased partners.

In the case of doctors with lists of 1,500–2,500 the position depends very largely on the type of practice—i.e., the percentage of private practice remaining and the possibility of extra remuneration for services outside the range of the N.H.S. Without these there must in many cases be considerable hardship, now partially relieved by the new Mileage Fund. Where the list is 1,500 or below, and particularly in rural practice or specialized practice—e.g., in a health resort where the majority of the patients have hitherto been private—there must be grave hardship which must be having a prejudicial effect on the health and well-being of the practitioner and his family. The addition to the Mileage Fund is a gesture, but not more, and pride alone is standing between a large number and a claim on the Inducement Fund. The high cost of living is not balanced by the existing capitation fee.

The basic salary in its interpretation is proving a most unsatisfactory business, and local medical committees and executive councils are floundering between laxity of interpretation and a serious attempt to assess the claims without inflicting hardship on those who do not claim for one reason or another. One would like to see it ruled that all doctors with lists under 500 should have the basic salary for two years, and if they have not secured a list of over 500 in that time the basic salary of £300 should be halved for another two years and then eliminated—this preventing gross abuse—but the money should not come out of the Practitioners Fund. In a firm the total number on the list divided by the number of partners should be the deciding factor. In addition, if the earned income from other sources is £500 or over, no basic salary should be available.

With regard to the capitation fee, the only possible solution must be a graded fee—based on the "betterment" factor—with a drop of, say, half a crown in the second thousand, and a further half a crown in the third and fourth thousand, and a drop after that of such degree as to discourage a ridiculously large list and encourage the addition of a further partner—with every support from the executive council—or the employment of an assistant. This plan would ensure a satisfactory living for the rural practitioner or the man whose health and inclinations were towards a small list, while discouraging "clearing-house" medicine. In any case it is beyond my comprehension to understand why anyone should seek to encroach further into the super-tax level in these times to the detriment of health and strength.

I cannot speak for the specialist, but as a member of a hospital management committee I hope regional hospital boards will ensure that full-time staff in particular, and junior part-time staff, have their permanent appointments confirmed by March 31 as promised, and that their remuneration will be commensurate with the increasing demands now being made on their services.

Finally, let the large majority of general practitioners who are not suffering other than the hardship of overwork demonstrate a willingness to be less selfish in the interests of their brethren who are really suffering in the ways I have detailed, and not try to obscure the issue or delay the final decisions of the Minister, as every additional month is a grave matter for the latter class, whose position in the majority of cases is entirely beyond their control.

The B.M.A. is the target for all, but after hearing the Secretary state the case the other day so skilfully and efficiently as to render questions superfluous I am still prepared to lend my fullest support, and evidently a fair proportion of the 60,000 others must be of the same opinion or they would not now be sending their annual subscriptions in the way we have heard of from Headquarters.—I am, etc.,

Bishop's Stortford, Herts

R. P. GAMMIE.

Remuneration in General Practice

SIR.—The profession is quite rightly concerned at the remuneration which it is receiving for work in the National Health Service, and much attention is being paid in this connexion to the report of the Spens Committee.

The Spens Committee was much perturbed over two fundamental facts which soon came to light early in their deliberations; first, that most general practitioners had to work far too hard and too long hours in order to earn the necessary income to educate their children and keep their wives and families in conditions compatible with their status; and, secondly, that under the National Health Insurance Act the remuneration was so inadequate that it had to be subsidized by private fees. The Spens Committee endeavoured to amend these shortcomings and tried to ensure that the lot of the general practitioner in the new Health Service would be better than his lot in the past. They felt that doctors should be paid sufficiently well to attract the right type of recruits into the profession, and that general practice should be so remunerated that it attracted its fair share of the best recruits which entered the profession. They felt strongly that remuneration should be adequate to leave the doctor some spare time not only for leisure and recreation but also for reading.

It seems to me, therefore, that when the question is asked whether Spens is being implemented or not there is more than one question to answer. It is not only how much doctors receive per quarter for the work which they are doing, but whether they are better off now than they were in N.H.I. days, and whether in fact they do enjoy some time in which they can call their own for leisure, exercise, and reading.—I am, etc.,

Bournemouth.

O. C. CARTER.

Advantages of Country Practice

SIR.—From Dr. M. D. S. Armour's letter (*Supplement*, Jan. 29, p. 52) suggesting a sliding scale of capitation fees, one is tempted to ask if the country doctor has no advantages over his colleague in the industrial areas. During the war I found that a great number of doctors in the Services were anxious to settle in country practices after their demobilization. This was still more obvious to me in 1946 when I was demobilized, as it was almost impossible to get into a country practice owing to the competition to buy. The answer was that most doctors preferred to live and bring up their families in pleasant country surroundings rather than in the crowded streets of suburbia or towns.

Surely the country doctor has a very real asset here which, though devoid of economics, is a blessing he cannot very well deny. A further asset, I suggest, is that the country doctor has the satisfaction of knowing that he at least is referred to as a medical sorting clerk. Having a letter from him is worth a lot.

Bedfont, Middx.

M.A.N.

Filling a Vacancy

SIR,—There is one aspect of the surrender of the right to buy and sell practices to which I have seen no reference. It is the difficulty created by the loss of the right to sell from the point of view of administration. Formerly when there was goodwill to put on the market there was a strong incentive for executors in a death vacancy to take steps to keep the practice together and so to sell it as a going concern. At present there is no such inducement, and in a short space of time a practice dissipates itself among neighbouring practitioners. When the young doctor arrives he finds himself with no patients. True, he pays nothing, but he gets nothing.

The authority—in Northern Ireland the G.H.S. Board—finds itself faced with a genuine complaint from the man who cannot survive on his meagre capitation fees—a position which even in populous areas may take long to rectify itself. Was he not better off when he could borrow or insure his life in order to make a sound investment, while the authority would have a contented medical man?—I am, etc.,

Belfast.

S. T. IRWIN.

A Comparison

SIR,—The following figures may be of general interest. I have on my list a few more old N.H.I. patients than new E.C.1 patients. Between July 7 and Dec. 31 the number of home visits to each section were: E.C.1, 765; N.H.I., 293. I was unable to keep separate records of the surgery attendances.—I am, etc.,

Funbridge Wells, Kent.

T. MACKINLAY MILLER.

Staffing of Hospitals

SIR,—Many doctors will have received a letter from regional hospital boards inviting suggestions on the staffing of hospitals after March 31, 1949. This is a matter of the greatest concern to us all, so in order to focus attention and stimulate discussion of some of the issues involved I append the memorandum I submitted in reply on Jan. 15.

I have put this point of view forward at various Representative Meetings and it has been widely supported, but its reaffirmation is rendered urgent by the "terms of reference" reported in the *Supplement* of Jan. 22 (p. 35) that the Consultants and Specialists Committee "shall be an autonomous body with full powers to determine policy and action on consulting and specialist and hospital matters through the administrative machinery of the Association. The decisions of the Committee within that sphere shall not be subject to approval of the Council or the Representative Body."

On the face of it this seems the complete abdication by the Council and Representative Body—i.e., general practitioners—of all right to any say in hospital policy or any share in hospital work except that conceded by the specialists. I think that this is a matter which needs very thorough discussion at the forthcoming S.R.M., and may I express the hope that this Special Meeting will not simply register protests but that out of its deliberations will emerge a constructive policy for the conditions of work as well as the remuneration of general practitioners? Both are essential if our patients are not to suffer and our skill deteriorate.

I need hardly add that this letter is not inspired by any opposition to the specialists and consultants. I do think, however, that in trying to claim the hospitals as their own special preserve they are doing a great disservice to the public and endangering the whole practice of medicine in this country. Abuses can be checked by co-operative effort, and it is just as important for the specialists to try to understand general practice as it is for general practitioners to try to help the specialists.

MEMORANDUM

In my opinion the outlook of the circular letter is altogether too limited and fraught with danger to the practice of surgery and the development of medicine in general. It appears largely to reduce the surgeon to his original status of one called in to do the work with his hands—what we now term a technician. The surgeon is to be the one to do the work fed into the hospitals by general practitioners and possibly other outsiders.

There is a view of surgery, which has for years been practised with growing success and satisfaction by practitioners, which looks on an operation as only one episode in the treatment of the patient, and one kept as far as is reasonable or practicable in the one pair of hands, with undivided authority and responsibility. It is the cultivation of this type of practice which leads a patient willingly to undergo the undoubted strain and anxiety of an operation or other hospital treatment without much upset. Cases in such circumstances come to operation much earlier than otherwise; so that though the practitioner may not have the same skill as his more specialized colleague he also has much less need to exercise it, for his patients do not as a matter of fact usually require drastic treatment. Even in such a practice, where it becomes necessary to send a patient to a large hospital away from the practitioner's care, or even to call in another surgeon to operate, there is always much greater difficulty in getting the patient to agree (especially in cases of going away), and this, more than anything else, is why the large hospitals get a much worse type of case than we do in the smaller hospitals, and also why so many surgeons seem to have such a poor idea of the capabilities of the general practitioner. Where the practitioner is cut off from all care of his patient before and after operation and the opportunity of being present at operation, with some responsibility for what is done, it is inevitable that he loses much of any original enthusiasm or skill. His powers of surgical diagnosis wither, and though, when seriously ill, the surgeon's skill and the care of the nursing staff may be great, the patient is actually in a worse state than he need have been.

It is rash to make unprovable assertions, but the total of patients' suffering and disability will probably be much greater under the theoretically efficient system outlined in the circular letter than it has, in the past, been in areas where the general practitioner has been allowed free use of the local hospitals, even with the inevitable mistakes that he may make, and which, incidentally, he has to live down and avoid in future if his practice is to prosper.

For this reason I strongly deprecate the suggestion that young resident medical officers should be attached to small hospitals, while the introduction of specialist surgeons needs watching with the greatest care if the standard of general practice is not to be depressed more than his presence may tend to raise it up. No practitioner worth the name will resent the help that more skilled colleagues can afford, and in the past this help has been freely afforded and also frequently sought. The greatest factor in improving the medical service of the country is probably the raising of the standard of the general practitioner, so that cases come earlier rather than later to attention.

Though this is doubtless the intention of the scheme outlined, I feel confident that its effect will be exactly the reverse, for practitioners as well as patients are human beings, with their own feelings and perhaps foibles. Any scheme which does not fully take account of these weaknesses is bound to fail, for however high our aims and ideals we still remain human beings and not machines. In time I think that the scheme will also prove as disastrous to the surgeon as to the general practitioner, for with the pressure of work that will be laid upon him he is likely to become more and more the pure specialist, with less time than ever for the humane study of the human material forcibly put at his disposal.

—I am, etc.,

Winsford, Cheshire.

W. N. LEAK.

The Betterment Factor

SIR,—As information becomes available of the Ministry's proposals to implement the Spens recommendations, which were considered capable of leading to acceptable levels of remuneration, it becomes clear that these recommendations are not couched in terms sufficiently precise to prevent the Ministry attempting to place an interpretation on them which, if not resisted, would result in levels of remuneration far below that intended by the Spens Committee.

Spens stated: "... such adjustments should have direct regard not only to estimates of the change in the value of money but to the increases which have in fact taken place since 1939 in incomes in other professions (my italics). In our judgment, it is only if corresponding changes are made in the incomes of general practitioners that the recruitment and status of their profession will be maintained as against these professions."

As judged by the report of the negotiations on the betterment factor (*vide Supplement*, Nov. 27, 1948, p. 192) it would appear that the Ministry is pointing to the incomes of some members of certain professions whose present remuneration is either less or little more than in 1939, and claiming because of this that the betterment factor which would be justified by the change in the value of money between 1939 and the present time must be abated. They draw attention particularly to the

salaries of certain Civil Servants which have been subject to increases varying from 9% to 13% only.

But of what relevancy is this, and even so, is it not common knowledge that (a) a wage freeze has been rigidly applied to the Civil Service; (b) the levels of remuneration offered by the Civil Service have been found insufficient to attract an adequate number of recruits of the necessary quality; (c) Civil Servants of the grades presumably referred to are now in process of claiming considerable salary increases? Similarly, of what significance is it to medical practitioners that as a result of the war some solicitors have insufficient work and are not making much money, or that some architects are overworked and are making a lot of money?

Surely the common understanding of the sense of the words in italics (in the context in which they appear) is that they are supplementary and potentiating rather than detractory or emasculatory to the words immediately preceding them in the quoted passage, and that they are included for the specific purpose set out in the last sentence of the quoted passage—i.e., to ensure apart from all else that this purpose is achieved.

In negotiations concerning the betterment factor it can be taken as axiomatic that the Treasury (as the paymaster of the country's largest employer) will have instructed the Ministry's negotiators to resist acknowledging the betterment factor at its true dimension, for the reason that if an equitable betterment factor were acknowledged it would put a lever at the disposal of those employed by the Government and local authorities by which adequate increases in salary could be justified and claimed. This is a position the Treasury will strive by every manœuvre to avoid. It is likely to prove a considerable misfortune to the prospects of medical practitioners that through no wish of their own, and due to circumstances over which they can exercise no control, they find themselves at the spear-head of the fight for the economic survival of the middle classes.

The Government's financial negotiators are probably the most expert in the world; they are able to draw on a vast accumulation of experience gathered as the country's largest employer and have available to them the most able statistical and actuarial advice. Furthermore, they have the peculiar advantage of not having to shoulder the direct responsibility of the consequences of imposing an unsatisfactory settlement. They will receive credit in proportion to the hardness of the bargain they drive and will be apprehensive of repeating the blunder made in settling the level of remuneration of the dental profession.

In these circumstances our Negotiating Committee have a task which no one will envy them. Without questioning their general level of ability, one wonders if they have the very specialized experience necessary to deal with the forces arrayed against them. Their only hope of reaching an equitable settlement is to insist, if a satisfactory betterment factor is not offered, that the whole matter goes to arbitration. Particularly must the Negotiating Committee avoid the bait of "generous expenses" as a set-off against an inadequate betterment factor. In a very short time, with no issue of principle at stake, such expenses would be whittled away as evidence was put forward that they were not incurred.—I am, etc.,

Moretonhampstead, Devon.

W. D. GLYNN JONES.

Subsidized Trainees

SIR,—Your attention has been called previously to the plight of ex-Servicemen who can now no longer buy into a practice and who have to accept assistantships at a salary often lower (*vide* your advertisements) than subsidized trainees—all this after, say, eight years qualified and perhaps five years in the war. Let us get this anomaly put right at the same time as another shameful discrepancy—rural G.P.s' salaries.—I am, etc.,

Caldicot, Mon.

P. M. FEA.

Widow's Superannuation

SIR,—I should like to draw your attention to an outstanding injustice in the provisions of the N.H.S. superannuation scheme (see *Superannuation Scheme for those Engaged in the National Health Service*, Section C, Para. 22). By working in the scheme I thereby forfeit my right to a widow's pension on my retirement should my husband predecease me. My husband is in partner-

ship in a rural practice, and I became a third partner prior to July 5 in order to establish my right to practise. I have three small children, and am therefore unable at present to do much medical work, but my intention is to do more as my family grows up. I now have a list of about 50 patients, and generally assist in the practice. I do not anticipate that my income is likely to be sufficient to earn me a pension equivalent to that which we confidently hoped would accrue to me as a widow, should my husband predecease me.

The Medical Defence Union advise me that, "If you are of the opinion that you would be better off if you were to receive a pension amounting to one-third of your husband's pension after his death than you would be by receiving the pension which you yourself have earned under the Scheme, I can only suggest that you cease to be a partner in the firm prior to the completion of ten years' service." In fact all forms of medical work would be closed to me barring private practice.

There must be a number of married women doctors, nurses, and medical auxiliaries under the N.H.S. to whom this regulation will come as an unpleasant shock. There will be some who earn pensions even before they marry, and many who will wish to do at least part-time work after marriage. Should their husbands happen to be employed under the N.H.S. regulations, they will be denied the benefits for which their husbands have paid large compulsory contributions and which other wives in other occupations will receive without question. It is a sad day when a woman doctor must choose between sacrifice of her career and forfeit of the security earned for her by her husband.—I am, etc.,

Langport, Somerset.

STELLA D. HENDERSON.

Abolish Out-patient Departments

SIR,—The time has come, has it not, to abolish the out-patient department. Originally intended for the treatment of the poor, its function now is to provide a consultant service, paid for by the State, for those who cannot or will not pay private consultants' fees (and who now attend by appointment). Those who pay, the consultants see in their own consulting-rooms. The equipment, service, and arrangements found adequate for private patients should surely suffice for the great majority of State patients. There is, in fact, no logical reason for any distinction between these (as to place and method) in consulting any more than in "general" or family practice.

Certain types of case—e.g., fractures—might require special arrangements; and the hospital would retain a small casualty department to deal with such accidents and genuine emergencies as are beyond the range of the family doctor. For the rest these expensive departments with their big staffs of registrars, assistants, residents, nurses, dispensers, secretaries, typists, clerks, telephonists, porters, and messengers are no longer needed.—I am, etc.,

Bristol.

E. WATSON-WILLIAMS

Evening Surgeries

SIR,—Dr. V. M. Seifert (*Supplement*, Jan. 15, p. 24) has invited opinions from other doctors. I am sure we all would like more leisure, more time for serious reading, better remuneration, less work, fewer expenses. But is that not taking a very one-sided view of things? Fitting one day's attendances into one morning surgery would strain any doctor's patience and endurance, overtax the capacity of a waiting-room that is already overcrowded this time of the year, help to spread infections more, and would ask for more trouble, more visits, etc. And what about the convenience of the patient? What about the working man who needs that bottle of cough-mixture to help him to carry on his work, and to whom an attendance at the doctor's surgery in the morning would mean loss of half or one day's pay?

Is Dr. Seifert not very dogmatic? "I never see children at night," "I do not troubles? Does it mean he ref them away that evening when th probably for an acute trouble. has been out working in the mo he is not giving advice in do asked for it?"

ates: "I never in domestic an and sends his surgery mother w does it is

Of course, abolition of evening surgeries would please the doctor's wife, perhaps the various Ministers, and even the doctor himself, but would it please our patients, to whom after all we are under contract and pledged morally to look after their physical and mental welfare? We would indeed be poor doctors and perhaps good Civil Servants.—I am, etc.,

Hull.

ROBERT HAAS.

Finalization

SIR,—In these days when nouns, adjectives, and even adverbs are "verbified" I should like to be quite clear as to Air Commodore Kyle's correction in the *Supplement* of Jan. 29 (p. 54). It appears that the W.A.A.F. have reverted to their old first-war title of W.R.A.F. and that the question of permanent commissions and retired pay has not yet been "finalized." Will it be correct to assume that "finalized" means "decided," or has it some wider meaning?

"As permanent commissions are visualized, but not so far finalized"—may this be translated as, "As permanent commissions are under consideration (or contemplated) but no decision has been reached"? I have been unable to find the verb "to finalize" in any dictionary, but "to visualize" is defined as "to make visible or visual, externalize to the eye" or "(v.i.) to call up a clear mental image." With "bastardized" words, "misconception" is always a possibility.—I am, etc.,

Brookwood, Surrey.

H. M. STANLEY TURNER.

"Natural Selection"

SIR,—There seems little doubt that many doctors are hard hit by the Health Service, but a great deal of doubt as to how this can be corrected. I feel that we must seek some way which will at the same time improve the standard of medicine and keep it the highest in the world.

Schemes such as a sliding scale benefit the man whose list is limited by laziness or lack of public confidence as much as he who limits his list to the number which he can look after thoroughly. Yet it is only this latter type who will give the service envisaged by the legislators—and he is suffering most from the legislation.

A way out of the dilemma is to leave it to each member of the public to decide whether his doctor is worth more or not by allowing us to charge fees as well. I know this is against Socialist dogma, but, faced with dogma or good doctors, I know the choice of the public. We should have the relative freedom of the New Zealander, but the Government would be free from the worry of "overvisiting."

It would work out along these lines. First, patients will soon leave the list of the doctor who overdoes the charging—no need for an expensive bureaucracy to check on him. Secondly, the lazy or inefficient man is automatically penalized and the good man rewarded (at no expense to the Government). There are, of course, difficulties. The man in a slum will have few he can charge, but this is balanced by his being able to care for a greater number, as his travelling time is nearly zero and most can attend the surgery, where facilities are all to hand. Again, in the sparsely populated areas that are also often poor, a very substantial mileage fee (enough not only for running a car, but also for saving up to replace it) will compensate.—I am, etc.,

Cromer, Norfolk

A. HENRY GREGSON.

Display of Hearing-aids

SIR,—The Minister of Health's latest instruction to regional hospital boards to prevent reputable British hearing-aid makers displaying their wares in the hospitals is in my opinion an acknowledgment by the Minister that the much-publicized national hearing-aid does not represent the last word in hearing benefit for the deafened public as has been suggested by the Ministry. Why should the Minister wish to prevent the public seeing at the hospitals the best British hearing-aids, which are for sale, to compare with the national instrument, which is made available free? Surely no thinking members of the public would for a moment consider purchasing a hearing-aid if they were offered one free which was equally attractive and efficient.

Does the Government not owe to the British hearing-aid makers, who are doing so much to capture the overseas hearing-

aid market, the right to have their instruments exhibited in hospitals, where, free from all sales propaganda, they can be inspected and tested by the deafened public if they so desire it? Even if the Government is not prepared to make it possible for the public, under the Health Service, to obtain assistance towards the cost of a commercial hearing-aid, surely they should not deprive them of the opportunity of seeing and comparing the products of private enterprise under the auspices of the medical authorities.—I am, etc.,

Oxford.

O. C. LEADBITTER,
John Bell and Croxden.

Supplementary Ophthalmic Service

SIR,—The statistics provide the answer to Dr. Cecil B. F. Tivy (*Supplement*, Jan. 22, p. 40). About 3 million patients had their eyes examined through the supplementary service during the first six months, and there are about 7,000 ophthalmic medical practitioners and ophthalmic opticians on the approved list. If the work were spread out evenly it could be handled fairly comfortably. The fees were calculated on the assumption that every patient would receive a full and adequate ophthalmic examination. Any conscientious practitioner should not permit the increased demand to persuade him to lower his standards or to rush the work. If an ophthalmologist or general practitioner only does supplementary ophthalmic work on one or two days per week he should restrict the number of appointments to that which can be attended to adequately. The spending of about half an hour on an eye examination does not ensure good work, but on the other hand it is very difficult to carry out a full routine examination in less than about half an hour if every part of the examination is done properly, including a full investigation into the state of the binocular apparatus.

Dr. Tivy's remark that only careless people entrust their eyes to opticians rings a little hollow at a time when ophthalmic opticians are continuing to examine the eyes of about 85% of the ametropic population to the complete satisfaction of the public and of the Minister of Health.—I am, etc.,

S. BLACK,
Director, Information Bureau,
Association of Optical Practitioners.
London, W.I.

SIR,—Dr. Cecil B. F. Tivy (*Supplement*, Jan. 22, p. 40) is of course perfectly right in his contention that "all this talk about spending an average of half an hour with each patient is only eyewash." Any competent refractionist, whether medical man or optician, can fix up a simple presbyope in a quarter of an hour, whereas a complicated case of astigmatism and muscle imbalance often requires three-quarters or even a whole hour spent upon him. In passing, it is worth noting that, if half an hour per patient is really essential, very few hospital patients have ever been adequately refracted.

The Ophthalmic Committee was surely wrong in allowing our remuneration to be assessed on such a basis. If we are to provide the same service as an optician, and no more, there is no valid reason why we should be paid at a higher rate. As to why our fees should in fact be the higher, Dr. Tivy's letter suggests the answer. He is apparently ready to spend an hour "making sure of an incipient glaucoma," which is something he, and not an optician, is qualified to do. As things are, however, he renders this extra service gratuitously, for under the Supplementary Scheme he is engaged as a refractionist pure and simple. Our higher fee can be justified only on the grounds that, as medical men, we are capable of making diagnoses and (within the limits imposed by lack of hospital facilities) of prescribing treatment. Even the old N.O.T.B. recognized this.

At the moment many opticians, faced with a patient requiring a medical opinion and/or minor treatment, rather than send the unwilling victim to hospital prefer to forward his O.S.C.1 to an ophthalmic medical practitioner and place upon the latter the onus of communicating with the patient's G.P. I submit that this is a very sensible procedure, since it preserves the liaison between two classes of medical men, saves the G.P.'s time and temper, and avoids cluttering up hospital O.P. departments with relatively minor conditions. I suggest that, rather than prepare sheepishly to accept a reduction of fees, the Ophthalmic Committee should be urging the Ministry to give *de jure* recognition to what is already a fact.—I am, etc.,

Birmingham.

J. H. AUSTIN.

Graduated Capitation Fee

SIR,—I was surprised to read in "The Secretary Reports" (*Supplement*, Jan. 15, p. 21) that an attempt had been made to reopen the question of the graduated capitation fee. The Secretary admits that one reason for the opposition to the universal basic salary was that it led to a tapering capitation fee position. The securing of the abandonment by the Ministry of the universal basic salary was, I always understood, a "great triumph of principle" upon which Headquarters congratulated itself.

The arrangement by which it is possible for smaller lists to draw a larger fee from a given global sum, whereas those with larger lists receive no less, is, I confess, beyond my understanding. The proposition that the ratio of expenses to receipts is likely to be higher in smaller practices is also a most dubious one. In fact, I have the testimony of an accountant that in all professional undertakings the exact opposite is the case. Whereas a doctor with a small practice may be able to carry on without any paid assistants, this is quite impossible in a large practice. This is not to say that we do not sympathize very sincerely with those who, through no fault of their own, have suffered a severe diminution of income.

The introduction of the graduated capitation fee, with all its inconsistencies and absurdities, is not, however, I am sure *not*, the correct method to assist them. But perhaps the best comment I can make is the following. At an exceptionally well attended meeting of the Wakefield Division held on Sunday, Jan. 16, 1949, the following resolution was carried unanimously: "That this meeting is opposed to the 'graduated capitation fee' in any shape or form."—I am, etc.,

A. G. JAMES,

Hon. Sec., Wakefield Division

SIR,—I read with pleasure the letter by Dr. M. D. S. Armour in the *Supplement* of Jan. 29 (p. 52). I agree with him that the only fair solution is sliding-scale capitation fees.

I have been working as an assistant in Birmingham for over 18 months now, and I do not think that the patient registered with a doctor whose list is swollen up to 4,000 and over is getting a fair deal. I have to see sometimes about 90-100 patients a day, not counting calls I have to make; and, even considering that we have three surgeries a day (270 minutes), on the average each patient is getting a little over two minutes per visit, including examinations, writing prescriptions, issuing panel notes, arranging hospital admissions, etc.—I am, etc.,

X Y Z.

Contact Between Hospital Bodies

SIR,—The letter from the editor of the *Hospitals Year Book* (*Supplement*, Jan. 22, p. 38) deserves the most careful consideration by every progressively minded person involved in the building up and maintenance of the new National Health Service. There certainly "has been plenty of communication, devolution, and directive downwards." Although one shudders at the thought of any more authorities, can it be gainsaid that the new Service is in mortal danger of becoming a series of independent units brought together only in so far as Instruments and memoranda issued in a steady flood by the Minister direct?—more and more memoranda, more and more officials, often with little knowledge and experience of the new highly paid duties which the Act, Instruments, and the memoranda necessitate, and a disgruntled medical profession, without which the whole machine will break, overworked and in many cases underpaid. There is need for those engaged in these multifarious duties to get away from the dead hand of bureaucracy and meet nationally and regionally, even locally, in freedom to compare experience and to discuss and formulate policy.

The British Hospitals Association provided a forum for the voluntary hospitals. In some parts of the country the regional and divisional hospitals councils established under the aegis of the Nuffield Provincial Hospitals Trust brought about immensely better relations between the local authority and voluntary hospitals. At a recent meeting of the committee of one of these councils there was an obvious feeling of reluctance to abandon the facilities which the council provided for discussion of hospital problems in the locality. The council, before it succumbs, is to debate the possible need for a consumers' council. While it is hoped that every board of

governors and hospital management committee will give proper consideration to patients' complaints, patients now have no contributory schemes associated with the hospitals to champion their cause.

Sir, is it not a matter of urgency that the new hospital authorities—boards of governors, regional boards, and management committees—executive councils, and local health authorities should be encouraged to send representatives (including representatives of independent hospitals, medical charities, and the general public) to regional—possibly sub-regional—meetings, that there should be a national council, an annual conference, and a national inquiry bureau, and that the statutory authorities should be permitted to pay their dues out of public funds? If they addressed their minds in the first instance to "costs and such economies as could safely be introduced without detriment to the Service" they might prove to be a handsome public investment—I am, etc.,

Bristol,

JOHN DODD.

Is This a Health Service?

SIR,—Most of the letters in the *Journal* recently are dealing with the financial side of the Service only, as far as it affects the general practitioners and specialists; not many of them mention the actual working of the Service. The efficiency of the Health Service is not proved by the large numbers of free dentures, spectacles, drugs, and appliances supplied, whether really necessary or not, but by the facilities obtained when a serious case needs investigation or urgent hospital treatment. I should like to mention a few cases which I had recently and which illustrate the real state of affairs.

A woman, aged 27, had a severe loss of blood and was practically exsanguinated. She needed an immediate blood transfusion. The local hospitals refused admission. She had to be taken by ambulance in a very critical condition to a hospital eight miles away for treatment.

A middle-aged man was operated on at a local hospital for a renal tumour. He was under observation at the same hospital as an outpatient. One day he sustained a fracture of the shaft of the femur. He was sent to the hospital for x-ray examination and treatment. He was x-rayed and sent by ambulance back home. The man was in agony for several days afterwards until he got admitted through the Emergency Bed Service into another hospital.

An elderly man was taken suddenly ill with severe pneumonia. He was very ill. He lived in a very small house; his wife was rather aged, and it was impossible to treat him at home. All the local hospitals refused admission. The Emergency Bed Service tried a whole day to admit him, and I was informed by them that evening that they were unable to get any bed for him anywhere.

A man fell off a scaffold and sustained an injury to his orbit and temple. He was referred to the eye department of a local hospital for investigation. He had to wait three weeks for an appointment. He was sent from there to the E.N.T. department and had to wait four weeks for an appointment. The E.N.T. surgeon referred him back to the eye department and the patient had to wait another three weeks before being seen.

I understand from other practitioners that this state of affairs is not confined to this particular locality and is universal. When a patient is sent for a barium-meal examination he has to wait over a month and even two before the result. For a report on an ordinary fracture one has to wait for over a week.

Figures have been published showing that the number of nurses has increased. The rate of sickness, as we can judge from the medical attendances, has not increased appreciably since last July. The only explanation of this deterioration must be that something has gone wrong with the hospitals. The almost cynical replies which one gets when trying to admit an urgent case to a hospital prove that the State control of hospitals converted the staffs into Civil Servants without any feelings for human sufferings. The patients themselves are very reluctant now of being sent to hospitals, as they can see the state of affairs; they try to keep away as long as possible from seeking advice.

If such state of affairs continues—and it looks as though it will go on for a long time—then we shall have not "the finest Health Service in the world" which was mentioned in the House of Commons by the Minister when the Bill was debated, but a very inferior one, which is bound sooner or later to affect the health of the people.—I am, etc.,

London, S.E.25.

Medical Practice in Western Australia

SIR,—As a new arrival in Western Australia I should like to give some information to colleagues in the U.K. who desire to come out here and settle in country-town practices.

I have visited half a dozen or so country towns of smaller size with populations of 1,200–2,000. Conditions are pretty primitive and doctors intending to come out should get detailed information about the place where they intend to work. There is electricity in most of these so-called towns, but only for lighting purposes, as the current is too dear for cooking, which has to be done on firewood, as gas is unobtainable. Almost all smaller towns are without modern sanitation, and occasionally—I have found it in one practice only—houses are provided with a septic tank. Water is another problem, and only a small part of the State—i.e., the south-west—is well provided with water, while other parts are dry and water has to be carted in long, hot, and dry summers.

Medical men are expected to equip the hospital with their own instruments—which are cheaper in England—and should be able to do major surgery, especially appendixes, hernias, and abdominal emergencies. Every Australian doctor does surgery and obstetrics in a country town, and the population expects a good surgical service from a general practitioner.—I am, etc.,

Perth, Australia.

W. WINTERTON.

POINTS FROM LETTERS

Reasonable Fees for Vaccination

Dr. G. H. M. FRANKLIN (Prees, Shropshire) writes: I have recently written to the county M.O.H. telling him that until a reasonable scale of fees for vaccination and immunization has been agreed between the Minister of Health and the representatives of the profession I am not prepared to render these services from now onwards. Might I urge all those doctors who are dissatisfied with the present arrangements to do likewise and so lend force to the arguments of our negotiators?

Basic Salary

Dr. N. WALSH (Scarborough) writes: The Minister of Health has been very clever in making the basic salary part of the "pool" allocated to all general practitioners. This is another of those things sprung upon us. As a result we are all made to contribute to the payment of basic salaries. It is only just, therefore, that a list of all people drawing basic salaries should be circulated to all doctors in each area. There are many rumours of abuse of the claim for basic salary, and the issue of such a list would go far to settle this matter. . . .

Association Notices

PROPOSED ALTERATION IN DENBIGH AND FLINT DIVISION

Notice is hereby given by the Council of a proposal to form two Divisions in the place of the present Denbigh and Flint Division as follows:

The East Denbigh and Flint Division: the area of the present Denbigh and Flint Division to the east of the Clwydian Range.

The West Denbigh and Flint Division: that part of the present Denbigh and Flint Division which lies to the west of the Clwydian Range, with the addition of Colwyn Bay, Old Colwyn, and Rhos-on-Sea.

Any member affected by this proposal and objecting thereto should write to the Secretary of the Association not later than Feb. 26, 1949.

CHARLES HILL,
Secretary.

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for research scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1949. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

Applications for scholarships must be made not later than March 31, 1949, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

Diary of Central Meetings

FEBRUARY

- 14 Mon. Armed Forces Committee, 2 p.m.
- 15 Tues. War Memorial Committee, 11.30 a.m.
- 16 Wed. Special Meeting of Council, 11 a.m.
- 17 Thurs. General Medical Services Committee, 11 a.m.
- 18 Fri. Joint Committee of B.M.A. and National Veterinary Medical Association, 2 p.m.
- 18 Fri. Drafting Subcommittee, 2 p.m.
- 24 Thurs. Occupational Health Committee, 2 p.m.
- 24 Thurs. Committee on Psychiatry and the Law, 2 p.m.
- 25 Fri. Film Committee, 2 p.m.

MARCH

- 1 Tues. Health Centre Committee, 2 p.m.
- 2 Wed. Dawson Williams Memorial Fund, 11.30 a.m.
- 2 Wed. Private Practice Committee, 2 p.m.
- 3 Thurs. Special Conference of Representatives of General Medical Committees, 10 a.m.
- 3 Thurs. Special Meeting of Council, 6 p.m.
- 11 Fri. Public Health Committee, 2 p.m.
- 23 Wed. Council, 10 a.m.
- 29 Tues. Special Representative Meeting, 10 a.m.
- 30 Wed. Special Representative Meeting, 10 a.m.

Branch and Division Meetings to be Held

BATH, BRISTOL, AND SOMERSET BRANCH.—At Royal United Hospital, Bath, Wednesday, Feb. 16, 8.30 p.m. Address by Professor Alexander Haddow: "Recent Advances in our Knowledge of Neoplastic Growth."

CITY DIVISION.—At Finsbury Health Centre, Pine Street, London. E.C., Thursday, Feb. 17, 8.30 p.m. Address by the Venerable the Archdeacon of London: "The Practice of Medicine and the Cure of Souls."

CLEVELAND DIVISION.—At Sparks' Café Royal, Middlesbrough, Thursday, Feb. 17. Address by Professor Ian Aird, preceded by supper at 7 for 7.15 p.m. New graduates, ex-Service practitioners, and members of the Stockton Division of the B.M.A. are specially invited to attend.

GREENWICH AND DEPTFORD DIVISION.—At Miller Hospital, Greenwich High Road, London, S.E., Wednesday, Feb. 16, 8.30 p.m. Dr. C. Edwards: "The Treatment of Some Common Neurological Conditions in General Practice." Members of the Woolwich Division are invited to attend.

HASTINGS DIVISION.—In Ball Room, Castle Hotel, Hastings, Sunday, Feb. 20, 3 p.m. Special meeting called to consider the following Resolution proposed by the Executive Committee of the Division: "That this Division demands a Special Representative Meeting for the sole purpose of deciding upon immediate action to raise the capitation fee to an equitable level. In the event of refusal by the Minister so to raise the capitation fee, mass resignation of all medical practitioners participating in the National Health Service should be called for by the Council of the Association on June 30." All medical practitioners in the area of the Division are invited.

ROCHDALE DIVISION.—Rochdale Infirmary, Monday, Feb. 14, 8.30 p.m. Clinical meeting. Dr. E. C. Easson: "Radiotherapy—Past, Present, and Future."

SOUTH-EAST ESSEX DIVISION.—At Southend General Hospital, Friday, Feb. 18, 8.30 p.m. B.M.A. Lecture by Sir Hugh Cairns. K.B.E.: "Closed Head Injuries."

STOCKPORT DIVISION.—At Stockport Infirmary, Tuesday, Feb. 15, 8.30 p.m. Mr. Wilson H. Hey: "The Prostate in General Practice."

SUNDERLAND DIVISION.—At Sunderland Royal Infirmary, Friday, Feb. 18, 8 p.m. Clinical demonstration by Dr. H. J. Bell, Mr. David Brown, and Dr. R. H. Vasey.

SUTTON COLDFIELD DIVISION.—At Sutton Coldfield Hospital, Monday, Feb. 14, 8.30 p.m. Inaugural meeting. Paper by Professor F. A. R. Stammers: "Costo-cervical Syndrome."

TUNBRIDGE WELLS DIVISION.—At Spa Hotel, Tunbridge Wells, Sunday, Feb. 13, 3 p.m. Dr. H. Guy Dain: "The National Health Service." Members from neighbouring Divisions are invited.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY FEBRUARY 19 1949

THE COST OF THE NATIONAL HEALTH SERVICE

BY

FFRANGCON ROBERTS, M.D.

(From Addenbrooke's Hospital, Cambridge)

In the Beveridge Report, 1942 (Appendix A, p. 201), the cost of a comprehensive health service for Great Britain was estimated by the Government Actuary at roughly £170 million. On a basis of population Scotland's share can be taken at £19 million, leaving £151 million for England and Wales. The National Government White Paper, 1944 (Cmd. 6502, Appendix E, p. 84), gave £132 million for England and Wales. The service contemplated was, however, incomplete, because it left £6 million to be provided for voluntary hospitals out of voluntary contributions and because "it would probably be several years before the net expenditure on the new dental services reached £10 million and on the new ophthalmic services £1 million"—a prediction very soon to be shown false. Allowing £4 million for a contemporary estimate for these two services, we get £142 million for a complete service. The White Paper, however, assumed the existence of 120,000 hospital beds, a figure which the subsequent hospital surveys showed to be an overestimate. The actual figures cannot be stated with precision, since in two out of the ten surveys the number is not stated. Calculating from the remaining eight, we may take the number of non-existent beds as 86,000. The White Paper estimate of £86 million for the total cost of the hospital services would therefore, if accurate, be £71 million, giving for the complete service £127 million.

The National Health Service Bill, 1946 (Financial Memorandum, p. iv), reckoned the cost of a complete service at £152 million. Two years later the Minister of Health, in answer to Sir Ernest Graham-Little (*Hansard*, April 8, 1948), gave an estimate of £230 million at current costs. The corrected estimates for a comprehensive service are therefore as shown in Table I.

TABLE I.—Estimates for England and Wales; Adjusted for a Comprehensive Service in All Cases

Year	Authority	£M
1942	Beveridge Report	151
1944	White Paper	127
1946	N.H.S. Bill	152
1948	Minister of Health	230

These figures take no account of projected capital expenditure. Health centres (2,000 at £187,000 each) will cost £374 million excluding site values and cost of equipment: the 69,000* extra hospital beds needed according to the Hospital Surveys will cost £345 million. Adding the cost of rebuilding, renovating, and re-equipping existing hospitals, we reach a figure far in excess of £1,000 million. Even though the capital cost be spread over a number of

*This figure is, as I shall show, a gross underestimate. Moreover it does not include mental beds.

years, the annual charge, including the cost of servicing, will reach an astronomical figure. What a commentary on our vaunted conquest of disease!

Meanwhile our faith in the official estimates, already shaken by their remarkable antenatal rise, is shattered by such neonatal estimates as have come in. The ophthalmic service is reckoned to be costing £20 million and the dental service £28 million, so that these two services alone are costing one-third of the Beveridge estimate and one-fifth of the 1948 estimate for the whole service. Let us therefore examine in retrospect the sequence of thought culminating in the present set-up, paying particular attention to the Beveridge Report, its *fons et origo*. We shall then see that all the official predictions are totally unreliable—(1) because they ignore the effect of the ageing of the population, (2) because they ignore the intrinsically expandable nature of hospital practice, and (3) because they are based on a false conception of health and disease.

It should be borne in mind that, according to the Beveridge Report (p. 162), "the primary interest of the Ministry of Social Security is . . . in finding a health service which will diminish disease by prevention and cure." On p. 104 it foresees that "there will actually be some development of the service and as a consequence of this development a reduction in the number of cases requiring it." These two factors are expected to cancel each other, leaving the cost for Great Britain in 1965 unchanged at £170 million. The author therefore seems to have had little faith in the ability of his scheme to fulfil its purpose. Later opinions were only slightly more realistic. The White Paper (Appendix E, p. 81) foresaw that the 1938-9 cost would be "considerably increased" owing to "some expansion of accommodation and services," higher prices and wages, and payment for specialist services in the voluntary hospitals. The Bill (Financial Memorandum, p. 1) expected that "considerable capital expenditure on the provision and expansion of hospital and other accommodation would be necessary as well as a high rate of expenditure and upkeep of existing buildings and renewal of equipment," but put this down to the arrears which had accumulated during the war.

The Ageing of the Population

One needs no medical training to know that the need for medical attention increases with age. Lord Beveridge evidently realized it, for he emphasizes the necessity of providing for the increasing risks of later life, and assures us (p. 8) that he has taken the ageing of the population into account. Yet in predicting a diminution in the need for treatment he ignores the warning which glaringly confronts him in his own Report. The relevant figures are shown in Table II.

TABLE II.—*Estimated Population of Great Britain by Age Groups (from the Beveridge Report, p. 91)*

	1941*		1971		Difference	
	No.	% of Total	No.	% of Total	In Nos.	In % of Total
Under 15	9,573,000	20.6	7,600,000	16.5	-1,973,000	-4.1
Men 15-64; Women 15-59, both inclusive	11,421,000	67.5	28,804,000	62.6	-2,617,000	-4.9
Men 65 and over; Women 60 and over	5,571,000	12.0	9,576,000	20.8	+4,005,000	+8.8
Total	46,565,000		45,980,000			

* I go back to 1941 because that year is the nearest to the date of publication of the Beveridge Report and because no provision has been made for the changes which have since occurred.

How could anyone fail to see that the addition of 4,000,000 to the pensionable group must result in a considerable increase in the incidence of disease? For the estimation of this increase certain data are available.

1. *Incidence of Degenerative Diseases.*—Holingsworth and Klem (1943) found that in people over 65 in the United States the incidence of degenerative diseases was 86.4 per 1,000. Assuming a similar incidence in this country, the number of sufferers would rise from 483,000 in 1941 to 829,000 in 1971, an increase of 72%.

2. *Domiciliary Attendance.*—In the United States Collins (1940) found that domiciliary attendance on people over 65 and on younger people was in the proportion of 6.0:2.7. The figures for this country given in the Registrar-General's Quarterly Returns are roughly the same. Simple calculation shows that if all medical treatment were domiciliary the amount for the whole population would increase by $\frac{6.0}{2.7}$, or 9.5%, from this cause alone.

3. *Bed-provision for the Chronic Sick.*—An investigation carried out by the Surrey County Council on behalf of the hospital surveyors of the London Area showed that of the beds for the chronic sick 75% were occupied by people over 64, and 25% by younger people. The number of beds needed is estimated in the different surveys at between 1.2 and 2.0 per thousand. Taking the lower figure, Table III shows that the increase needed between 1941 and 1971 is 28,000.

TABLE III.—*Beds Required for Chronic Sick (On a Basis of 1.2 per Thousand)*

Year	Men over 64 and Women over 59			Others			Total Beds
	No.	% of Popn	Beds	No.	% of Popn	Beds	
1941	5,571,000	12.0	42,000	40,994,000	88.0	14,000	56,000
1971	9,576,000	20.8	72,000	36,404,000	79.1	12,000	84,000

Similarly, taking the higher figure, the increase is 47,520. Whatever the figure, the increase is 50%.

Lord Beveridge seems to have visualized a population after an active life of successive illnesses and restorations to health entering into healthy old age which eventually terminates in clinically blameless death. The hospital surveyors of the Eastern Area hope for a diminution in the incidence of degenerative diseases for improved home care and earlier diagnosis. But it has yet to be proved that home care is more economical than institutional treatment, and we have little evidence that earlier diagnosis will make tissues less liable to degenerate or old bones less liable to break. It is obvious to everyone that to our powerlessness to prevent these occurrences must be added our remarkable progress in retarding malignant and degenerative processes, and that, although this progress must itself in due course become retarded, we have still a long way to go before the limit of our achievements is reached. We shall certainly see a more widespread application of radio-

therapy and physiotherapy, which, whether really effective or not, will be valued, and therefore demanded, for the psychological satisfaction which they give not only to the recipients but also to their relatives. The transference, so to speak, in 30 years of 4,000,000 from the younger to the pensionable age group (a number which may well be increased by medical progress) cannot fail to impose a heavy economic strain on a working population diminished by 2,600,000 according to the official estimates, which, it should be noted, take no account of the further reduction that will result from Government-sponsored emigration on a large scale and from the raising of the school-leaving age to 16. We may derive a grim consolation from the easing of the burden owing to the diminution of 1,970,000 in the number of children under 15.

The Expansion of Hospital Practice

Prior to the last war the medical services undertaken by the State, apart from the activities of the Medical Research Council, were practically confined to the institutional treatment of chronic sickness, infectious and mental diseases, tuberculosis, and to part of general practice. With the exception of the surgical treatment of tuberculosis the cost of these was almost static, fluctuating only with the cost of living. Any undue rise in the cost of the general practitioner service could be checked by penalties for over-prescribing. When the State proposed to undertake the treatment of the acute sick it was assumed that this too was almost static. "There will be some development of the service," says the Beveridge Report. "There will be some expansion of accommodation and services provided (e.g., for cancer)," says the White Paper [italics mine].

These comforting words betray a singular ignorance of the most outstanding characteristic of the voluntary hospitals—namely, that their activities were determined by the application of science, which, as I have shown (Roberts 1948), resulted in the expansion with accelerating velocity of every branch of their work without exception. The growing demands made upon them they met by spending up to and often beyond their income, proudly displaying their adverse balances as a measure of their success and as a basis for appeals for more generous support. There was therefore every reason to suppose that when their financial embarrassments were removed their expansion would be still further accelerated. But owing to defective historical sense none of the official publications show any realization of this state of affairs, though it must have been obvious if only from experience gained in the Emergency Medical Service. Estimates were based on the then existing expenditure plus the amount due to arrears which had accumulated during the war. Had they been based on the rate of growth they would have furnished a more reliable indication of the magnitude of future commitments.

Misconceptions about the Nature of Disease

To sociologists disease has always appeared as something which causes poverty. It is one of the five "giants" (to quote the Beveridge Report) which threaten social security through the cost to the invalid and the economic consequences to him and to his dependants. Hence the first steps at mitigation were concentrated, in the National Insurance Act, on the wage-earner. In the Beveridge Report this view of disease receives its fullest expression. This can be seen in the repeated emphasis on "restoration to health" and the importance of rehabilitation. Steps must be taken "to prevent interruption or destruction of earning power from leading to want." According to the International Labour Office the principal object of sickness insurance is to restore health and working capacity. On this simple view the community can be divided into two

roups: those who are well and able to work, and those who are unwell and unable to work. Disease is something people recover from, and the doctor's duty is to expedite that recovery so that they may resume their labours.

For taking this restricted view sociologists cannot be blamed. Untrained in biology and medicine, they are incapable of seeing health and disease in their proper setting. The fault lies in ourselves. In what is known as Social Medicine we have joined hands with them in investigating the effect of social conditions upon health, but we have neglected the wider problem. We have failed to formulate any doctrine embodying the true relation between medicine and all the elements of which civilization is composed—human nature, social progress, standard of living, control over Nature. This extremely intricate relation must now make an effort to unravel, a task we can best begin by taking one by one the delusions under which sociologists labour.

What is Health?

The Beveridge Report, as we have seen, conceives ill-health as something which threatens social security. But when it comes to the means of treating ill-health it disregards this restricted conception for one which is all-embracing. "For every citizen there must be available whatever medical treatment he requires, in whatever form he requires it, domiciliary or institutional, general, specialist, or consultant. . . ." We thus have in the same report two widely differing conceptions, and it is in the one which separates them that the Health Service is most likely to founder. It therefore seems desirable to try to define health. The anonymous writers of the *Report on British Health Services in the Political and Economic Planning (P.E.P.) Series (1937, p. 395)* state that "we can only claim scientifically to know what health is." Their confessed incapacity, however, does not deter them from expounding, in common with many other writers, the ideal fiction of "positive health." This seems to be a permanently ecstatic state which will inevitably ensue from removal of adverse social conditions, from more intensive health propaganda, the training of more and better doctors, and the building of bigger and brighter hospitals. Maintaining that health can be regarded only as a neutral zero state, I suggest the following definition:

Within the limitations of diagnosis good health exists, when the separate organs of the body are functioning within the recognized normal range, and when the integration of their functions permits growth and physical and mental activity within the normal range; (2) when the activity of the micro-organisms for which the body is the natural habitat are sufficiently counteracted so that they are prevented from impairing functional powers; and (3) when the physical and mental stimuli constantly arriving from the environment do not appear to impair structure or function at the moment, and, though individually subliminal, do not appear to be exerting a cumulative effect in impairing them in the future.

Whatever its imperfections, this definition is, I think, at least realistic. It recognizes that the fight against disease is one aspect of the struggle for existence, like the quest for food and for protection against the violence of Nature. The struggle, so far from becoming easier, must inevitably become harder at every step owing to our inherent moral and physical infirmities, our mortal nature, and the bounds of time and space. We cannot conquer Nature, for the simple reason that we are ourselves part of Nature; we can only come to terms with her, and she drives a hard bargain.

Social and Economic Conditions

It is necessary to remember," says P.E.P., "that there are often two alternative policies for dealing with ill-health

—either to treat the cases or to deal with the social and economic conditions producing the cases." If by "social and economic conditions" is meant poverty I can only reaffirm categorically that with the possible exception of tuberculosis none of the major diseases and few of the minor ailments are in any degree attributable to this cause. Housing conditions are still deplorable in many places, but preventive medicine, by making the slums, as it has made the jungle, more habitable, has made their abolition less insistent. As regards psychological disorders, can we, influenced by the prevailing philosophy of determinism, indefinitely attempt to adjust the environment to the individual, bearing in mind the function of the environment in the formation of character? Does our growing knowledge of the workings of the mind keep pace with the new problems for ever arising in an age when the increasing complexity of civilization inevitably breeds new sources of friction in human relations and when increasing self-consciousness makes man more critical of his environment though not more critical of himself? "The fault, dear Brutus . . ."

Industrial diseases present a similar problem. If our task were confined to the elimination of those which have long existed it would be formidable enough. We must remember, however, that industry is not static. Scientific discovery leads society to engage itself in the production of ever more complex chemical substances the ill-effects of which are discovered only by experience. Even more formidable are the risks involved in the industrial uses of x rays and γ radiation, and in the production of isotopes and radioactive substances. The protection of employees and the prevention of contamination of air, water, and earth require a cleansing ritual which is fantastically elaborate. Nor is it merely a matter of disease which is immediately apparent, for there is reason to fear the advent of pathological effects delayed by years and even the possibility of danger to succeeding generations. As man, spurred by curiosity and the struggle to survive, penetrates ever more deeply into Nature's secrets she exacts an ever heavier toll. With these increasing hazards, which become a progressively more integral part of industrial life, medicine strives frantically to keep pace. Danger is always one move ahead of prevention.

Disease and Working Capacity

"Disease and accidents must be paid for in any case, in lessened power of production and in idleness" (Beveridge Report, p. 158). This sweeping statement is a travesty of the truth. It ignores all those conditions which have no effect on earning power—minor and localized skin diseases, such as digital warts and birth-marks, minor errors of refraction in the illiterate, the loss of a tooth, and baldness (for which wigs are supplied in duplicate), to name only a few of the vast number for which correction is now being demanded. It ignores the fact that medicine is a luxury as well as a necessity. It ignores the coexistence of incurable neurosis with unimpaired functional efficiency. We all know the neurotic woman who, when asked whether her symptoms interfere with the performance of her household duties, replies with an indignant denial, the very suggestion being a reflection both on her sense of duty and on her capacity for martyrdom.

Underlying this view is the assumption that health is something which all desire. I once heard a distinguished sociologist speak of a friend as "enjoying ill-health." From his sympathetic tone it was clear that he was using the expression in its figurative sense and that he was ignorant of its true and literal meaning. This humourless view seems to be general among sociologists. The writer

PEP say: "Many of the costs of ill-health cannot be measured in money. The subjective element in the endurance of pain and sickness cannot be estimated. It is impossible to say what contribution might in happier circumstances be made to the community by that regrettably large body of persons who 'enjoy indifferent health,' whose energy is all absorbed in struggling through the daily round."

An associated idea is that health is an end in itself. Health, however, is not an end but a means to an end, the end being the full life, though it does not follow that the full life which results is necessarily the good life. Good health is, I imagine, as essential to a burglar as it is to a bishop. But if health is a means to an end there must be an end worth having. At the present stage of civilization the best way to diminish the vast amount of imagined ill-health is the removal of sources of frustration and the encouragement of initiative, independence, and self-respect.

The Standard of Living

National prosperity, it is believed, is necessarily increased by the advancement of medicine. The truth is that it is both increased and diminished. It is increased by treatment which secures without disproportionate expense complete recovery in the young and middle-aged; it is diminished by measures which promote the survival of the unfit without making them fit and by those which merely prolong invalidism at a level incompatible with functional efficiency. The question is, which of these two actions predominates? I believe it depends upon the stage of development to which medicine and civilization have attained. At lower stages the effect is a pure enrichment of society, but, as civilization advances, the opposite factor exerts an increasing back-lash until at a certain point national prosperity is threatened. I do not say that we have reached this point, but we are certainly moving towards it. We are cured of the simpler and cheaper diseases to fall victim later on to the more complex and more expensive. This is the price which society pays for lengthening the expectation of life.

It is hoped that as the Health Service improves the need for it will diminish, and that this factor should lower the cost (Beveridge Report, p. 104). This is another way of saying that disease still threatens security because treatment is inadequate. Study of the past gives no grounds for this belief. The phenomenal development of hospital practice has, as I have shown (Roberts, 1948), involved an increase in cost per patient far exceeding the rise in the cost of living, a fact which disproves the contention that the increase is due to the more widespread dissemination of existing facilities. The determining factor is the increasing application of science, which, if given free play, will without any doubt always outrun provision. In 1860 England and Wales, with a population of 20,000,000, had just under 11,000 doctors, practically all of whom were general practitioners. Their average income was certainly not more than £500. The total amount spent by patients was thus £5,500,000, including the cost of drugs. To-day the general practitioner service is costing more than £40 million excluding the cost of drugs and administration. In 1860 hospitals, except in large cities, were small and cheaply run, and in country towns almost non-existent. Workhouse infirmaries administered only the barest medical necessities. The country's total medical bill must have been well under £10 million.

It can indeed be laid down as a law, that in a free economy the cost of medical treatment rises with the standard of living. This is because medicine is more successful in treatment than in cure; because medicine is

partly a luxury and its cost therefore rises with the amount spent on other luxuries, as Dickinson (1947) has shown. because those engaged in medicine are themselves part of society and share its fortunes; and because medical progress and a rise in the standard of living are both due to the same cause—the advancement of science. Science which gave us radium and penicillin also gave us television and the electric washer. It follows that in a free economy if the standard of living were to fall the cost of medical treatment would fall with it. In a planned economy there is no knowing what would happen; it would all depend on the planners. Certain it is that if an attempt were made to maintain or increase the cost of medical treatment the fall in the standard of living would be catastrophically accelerated.

Let us here note one very significant fact. Just at the moment when the provision of individual economic security is accomplished comes the realization of the precariousness of our national economic security. This is reflected in (among other ways) the change of emphasis in appeals for voluntary support. It being no longer necessary to shock us into generosity with pictures of disease and consequent poverty or of poverty and consequent disease, our feelings are harrowed by statistics showing how disease impedes national recovery. The Empire Rheumatism Council, for instance (*The Times*, Nov. 3, 1948), tells us that 3,000,000 weeks of work are lost each year by the insured population through rheumatic disease. The meaning of this should be clear to all. It is that from the struggle for existence there is no escape. Nature sees to that. Legislation can remove it from the individual but only by transferring it to the State.

The Moral Implications

"It is a logical corollary to the receipt of high benefits in disability that the individual should recognize the duty to be well and to co-operate in all steps which may lead to diagnosis of disease in early stages when it can be prevented" (Beveridge Report, p. 158). This obligation, which incidentally can be read as a direct encouragement to abuse the Service, means more than refraining from malingering, a subject on which writers on industrial medicine are eloquent. It means that citizens will arm themselves with the moral shield and buckler against disease; that they will conquer the lusts of the flesh; that they will suffer neither their bones to be broken in drunken brawls nor their livers to become cirrhotic by chronic addiction; that they will not use their disabilities to tyrannize over their fellow-men; that they will always allow themselves to be made efficient members of society by surgical operation rather than remain permanent charges on the community by their refusal; and that they will think twice and even three and four times before sending for the doctor. The stability of the Health Service in fact requires a tremendous moral uplift the like of which mankind has never seen, an uplift which even ministerial supplications will be powerless to achieve. Failing this happy transformation of human nature the true logical corollary is the application to our weaker brethren, and perhaps to us all, of measures which, to put it mildly, will be anything but pleasant.

Medicine Considered as a Commodity

Sociologists maintain that medical treatment is above economic considerations. The Beveridge Report (p. 16) says that full prevention and curative treatment must be available "without an economic barrier at any point." According to Levy (1944), "economy in medical treatment contradicts the very foundation of medical science." This however, is true only in regard to treatment which results in partial or complete restoration of functional efficiency.

its application to complaints which do not impair functional efficiency and to diseases which are incurable and which cause total and permanent incapacity is a different matter. It will clarify our minds if we consider the differences and resemblances between medicine and other commodities—food, clothing, housing, and fuel. The chief differences are these: First, the direct cost of medical treatment is an addition to normal requirements. Secondly, allowing for individual variation in the conception of what is essential and what is extravagant, and for the fact that the luxuries of to-day become the necessities of to-morrow, the minimum requirements of other commodities can be at least roughly assessed. We know the amount of clothing, fuel, and food needed to keep us warm, dry, and well nourished. In contrast, the need and value even of the essentials of medicine are usually impossible to assess.

Thirdly, we know the cost of food and clothing; we can find out exactly the cost of repairing a house or a coat and we have a reasonable guarantee that the repair will be successful. In medicine we have no such assurance. The cost cannot be estimated nor can a cure be guaranteed. When an article reaches obsolescence we can decide whether to repair it or buy another; with our bodies we have no option, and the chances that repair will be successful diminish with the years. Fourthly, though fancy articles command fancy prices, the cost of food, fuel, and clothing is in normal times subject to little fluctuation, since it depends on the cost of labour and raw materials and is regulated by the law of supply and demand. Medicine, however, contains within itself the means of its own expansion—namely, the expansion of science on which it is based—an expansion beyond the control of market conditions and of which the only certainty is that it will continue indefinitely.

The resemblances, if less obvious, are no less real. Medicine, like other commodities, consists of a core of essentials surrounded by inessentialities extending to luxury and extravagance. Illness makes many people less able to pay the cost of treating it, but it also makes them less able to pay for rent, food, and clothing. The means of providing all these commodities, including medicine, comes from the same sources—personal and national wealth.

The consequences of failing to understand these differences and of ignoring the resemblances are plain for all to see. At a time when food and clothing are rationed, when the housing shortage causes immense difficulties, and when the coal shortage constitutes the gravest threat to our standard of living, medical treatment is provided in abundance with no regard to economy. In unemployment pay, old-age pensions, and the death gratuity, where costs can be readily determined, the benefits are based on the minimum needed to keep our bodies in reasonable comfort and in due course to bury them with reasonable decorum. Moreover, for entrants of advancing years there is a minimum period of contribution before full benefits can be obtained, so that many people have to be helped by National Assistance. But in regard to sickness, the cost of which cannot be ascertained with anything approaching accuracy and of which the only certainty is that it will increase with accelerating speed, the State has underwritten an unlimited liability.

Conclusions

I believe that through ignorance and miscalculation in its preparation the cost of the Health Service has been grossly underestimated, that when in full operation it will be no less than £500 million, and that in future years it will rise to an even higher figure. Whatever the exact figure, I am firmly convinced that at the present rate of expenditure it will involve us in national ruin. The

alternative is hardly less comforting. It is that a limit will be set by shortage of personnel and materials. This means (mark it well!) that medicine will be rationed and controlled, and there is no reason for supposing that nationalized medicine possesses any moral superiority rendering it immune from the vices which rationing and control invariably bring in their train.

There have been occasions when nations have been decimated by disease. They have often recovered, but changed in social structure. The Black Death, for instance, by creating a shortage of labour destroyed the feudal system. In the twentieth century civilization is faced with a threat unique in its history, the existence of more ill-health than it can afford, due not to any temporary calamity but paradoxically to the advance of civilization itself. Society has opened a new Pandora's box, releasing new diseases of its own creation and with them innumerable new methods of treating all the diseases which it cannot cure.

The stupendous problem thus created calls for the exercise of the highest intelligence. Our duty as a profession is clear. We must teach our students and the lay public that the fight against disease is part of the struggle for existence; that medicine is not above economic law but strictly subject to it; that the claims of health, so far from being absolute, are relative to national well-being; that the country will get not the finest Health Service in the world but the Health Service which it deserves. We must not allow absorption in the daily round to prevent us from counteracting the hysterical clap-trap of demagogues, the impracticable visions of idealists, or the false premises of academic theorists. We must proclaim the faith that is in us, the faith inspired not by the Blue Books but by the bedside, not by Sidney Webb but by Hippocrates, not by the London School of Economics but by the Island of Cos.

The Poisons Board has made certain recommendations to the Secretary of State for the further amendment of the Poisons List: and of the Rules made under Section 23 of the Pharmacy and Poisons Act. He therefore proposes to make Statutory Instruments which will effect the following changes in the law relating to poisons: 6-morpholino-4: 4-diphenylheptane-3-one and its salts will be added to Part I of the Poisons List. Dinitrocresols will be taken out of Part I and added to Part II of the Poisons List. Bis-bis-dimethyl-aminophosphonous anhydride, diethyl-paranitrophenyl thiophosphate, hexaethyl tetrophosphate and tetraethyl pyrophosphate will be added to Part II of the Poisons List. 6-morpholino-4: 4-diphenylheptane-3-one will be included in the First and Fourth Schedules to the Poisons Rules. Dinitrocresols will be exempt from the restrictions which apply to First and Fourth Schedule poisons when sold in the form of agricultural and horticultural insecticides or fungicides. Such preparations will be excluded from the general exemption from control of all substances containing dinitrocresols and not being preparations for treatment of human ailments; they will be the only preparations containing dinitrocresols and subject to the control of the poisons law which may be sold by listed sellers of poisons. The four phosphorous compounds named will be exempted from control when sold in any form other than agricultural or horticultural insecticides or fungicides. These preparations, and the similar preparations containing dinitrocresols, will be subject only to the restrictions imposed by their being included in Part II of the Poisons List and in the Seventh Schedule to the Poisons Rules. The form of words with which they are to be labelled will draw attention to the danger of using the preparation in an enclosed place and of allowing it to come into contact with the skin. Rule 30 will be extended to include insulin in the list of poisons which may be manufactured under the supervision of a duly qualified medical practitioner.

PEPTIC ULCER IN GLASGOW

A HOSPITAL SURVEY

BY

R. A. JAMIESON, F.R.C.S.Ed.

W. E. SMITH, M.A., M.B.

AND

L. D. W. SCOTT, M.R.C.P.

(From the Peptic Ulcer Clinic, Glasgow Western Infirmary)

From an analysis of reports from hospitals in Great Britain Nicol (1941) suggested that there is a geographical variation in the relative frequency of gastric and duodenal ulcer. Doubtless other geographical variations would come to light if sufficient information were available. Unfortunately the majority of hospital reports deal exclusively with in-patients, and if the criteria for admission vary from one hospital to another the omission of out-patients may lead to serious error. So far the only complete survey of hospital patients with peptic ulcer in this country was made in the Greater London area (Avery Jones and Pollak, 1945). We present for comparison the experience of a hospital in the West of Scotland.

Methods

A survey was made of the out-patients and in-patients with peptic ulcer attending the Western Infirmary, Glasgow, during the two-year period from May 1, 1946, to April 30, 1948. For the purpose of the survey it was necessary to adopt an arbitrary standard of diagnosis. For out-patients the diagnosis was taken as established when an ulcer had been demonstrated radiologically, and for in-patients when ulcer was the final diagnosis made by the clinician in charge. Out-patients were interviewed daily immediately after they had been x-rayed, the count of out-patients was complete as compared with the barium meal logbook, but, as was inevitable in a busy department, a few patients escaped interview. The count of in-patients was made by visiting each ward once a week, and virtually all the ulcer patients were interviewed save those who died within a few days of admission. The information obtained was recorded on punch cards to facilitate sorting. Care was taken to avoid counting any patient more than once, and (again to avoid duplication) out-patients subsequently admitted were classed as in-patients. Patients known to have a peptic ulcer but seeking advice for unrelated disease were excluded. Finally, to allow comparisons to be made with previous reports from other hospitals, we have wherever possible appended to our overall figures the data relating separately to out-patients and in-patients. This has proved all the more necessary as out-patients and in-patients differ (as we shall show) in respect of age, sex, site of ulcer, and complications.

Number and Sex Ratio of Patients

During the two-year period mentioned it was found that 3,258 ulcer patients passed through the hospital, comprising 2,286 out-patients and 972 in-patients. Figures for the total hospital attendances are not available for the exactly corresponding period, but during the two calendar years 1946 and 1947 the number of patients attending the general medical and surgical out-patient departments was 25,333 and the number of in-patients in the general medical and surgical wards was 22,425. Peptic ulcer accounted for a notable proportion of all hospital patients, especially in the out-patient service. To the 2,286 out-patients with ulcer must be added a further 244 out-patients who were subsequently admitted to the wards: peptic ulcer therefore

accounted for some 10% of the total out-patients. Among in-patients it accounted for 4.3%.

There were 2,526 males and 732 females—a ratio of 3.5 males to 1 female. This was considerably lower than the ratio of 4.7 to 1 given by Avery Jones and Pollak (1945); it is a matter for regret that comparable estimates from other hospitals have not been published. A point of interest in our series, to which further reference will be made, was the different sex ratio in out-patients as compared with that of in-patients: in out-patients there were 3.1 males to 1 female, and in in-patients 4.5 to 1.

Age and Site Distribution

The age distribution of the ulcer patients attending hospital is shown in Fig. 1. The large number of patients

Fig. 1.—Peptic ulcer: Age and sex incidence. In 53 cases the ulcer site was not stated and in 4 cases of gastric and 17 of duodenal ulcer the patient's age was omitted.

(some 60%) concentrated between the ages of 30 and 45 is worthy of notice. This emphasizes again the economic importance of peptic ulcer as a cause of chronic ill-health at a time of life when its victims are at the height of their wage-earning capacity.

The great preponderance of duodenal over gastric ulcer is also well shown in Fig. 1, and the overall ratio was 2.5 duodenal ulcers to 358 gastric ulcers, or 7.7 to 1. The preponderance was greater in males than in females—

males it was 9.5 to 1, whereas in females it was only 4.4 to 1. The ratio differed also in out-patients as compared with in-patients.*

An observation of great interest was the striking difference in the ages of patients with duodenal ulcer as compared with those with gastric ulcer. Thus in males the mean age for duodenal ulcer was 41.8 years and for gastric ulcer it was 47.6. In females the difference was even greater—namely, 42.0 and 51.5 years respectively. These large variations seem to reflect a real age difference in the incidence of duodenal and gastric ulcer. Strong support for this inference is provided by the evidence presented in Fig. 2 and Table I, in which duodenal and gastric ulcers

FIG. 2.—Peptic ulcer: Age at onset of symptoms.

TABLE I.—Age at Onset of Symptoms

Age (Years)	Gastric Ulcer	Duodenal Ulcer
5	0	5
10	2	48
15	13	226
20	19	413
25	38	421
30	42	391
35	34	292
40	42	231
45	37	169
50	24	103
55	23	74
60	17	55
65	11	33
70	4	11
75	3	4
80-84	0	1
Age not stated	49	256
All ages	358	2,763

are contrasted in respect of the age at onset of symptoms. It will be seen that symptoms begin at an earlier age in duodenal ulcer than in gastric ulcer.

Complications of Peptic Ulcer

Of the total 3,258 patients dealt with during the survey, 1,237 (38%) were undergoing treatment for a complication of peptic ulcer or had suffered a complication at some time in the past. Of the common complications we have classified perforation and haemorrhage, but have not felt justified in attempting to classify stenosis. Patients requiring operation for advanced stenosis have been classed with patients requiring operation for other intractable disability under the general term "elective operation." The incidence of complications (past or present) is shown in Table II.

It will be noted that the complication rate was much higher among in-patients than among out-patients. It is indeed hardly a matter for surprise that in-patients should

TABLE II.—Incidence of Complications

	Out-patients		In-patients		Total
	Male	Female	Male	Female	
Uncomplicated	1,208	414	159	42	1,823
Perforation	115	3	225	17	360
Haemorrhage	170	71	145	56	442
"Elective operation" ..	33	14	85	30	162
Perf. and haem.	25	1	36	5	67
Perf. and elect. op. ..	7	—	53	1	61
Haem. and elect. op. ..	14	5	63	20	102
Perf. and haem. and elect. op.	9	—	29	5	43
Unstated	149	48	1	—	198
Totals	1,730	556	796	176	3,258

comprise chiefly those who have suffered some complication of their ulcers. However, when it is shown that only one out of five of the out-patients suffered a complication as against four out of five of the in-patients, it becomes clear that out-patients and in-patients represent different sections of the ulcer community. We believe that it is because in-patients are selected mainly on the basis of past or present complications that they differ from out-patients in so many respects; the outstanding differences in age, sex, and site of ulcer have been stressed throughout this report.

The commonest complications were perforation and haemorrhage; the relative frequency of these is shown in Table III. In gastric ulcer haemorrhage was commoner

TABLE III.—Relative Frequency of Perforation and Haemorrhage

	Perforation		Haemorrhage	
	Males	Females	Males	Females
Gastric ulcer	28	9	51	30
Duodenal ulcer	456	23	294	114

than perforation in both sexes. In duodenal ulcer, however, there was a conspicuous sex difference: in males perforation exceeded haemorrhage in the ratio of 456 to 294, or 1.5 to 1, whereas in females perforation fell short of haemorrhage in the ratio of 23 to 114, or 1 to 5. This remarkable sex difference in duodenal ulcer remains unexplained. If it be accepted that duodenal ulcers which perforate are situated anteriorly, whereas those which bleed are mainly posterior, it would seem that women must have a relative immunity from ulcer of the anterior duodenal wall. This interesting speculation merits further investigation.

Site of Ulcer and Social Status

It has been claimed (Morris and Titmuss, 1944) that among the poorer classes there is a disproportionately large number of deaths due to gastric ulcer as compared with duodenal ulcer. It was of interest, therefore, to arrange our patients according to social status and site of ulcer, but it can be said at once that we were unable to confirm this finding. For the social grading we have used the scheme of the Registrar-General for England and Wales (1931); Grade I includes the professions, Grade III skilled artisans, Grade V unskilled workers, and Grades II and IV are intermediate.

Table IV shows that the observed and expected numbers were in general in close agreement. There was no systematic surplus of gastric ulcers in Grade V, and indeed in two of the three age groups there was actually a small deficit.

Lastly, we examined the possibility that peptic ulcer in women might be commoner in the unmarried because they tend to have the same conditions of work and meal-times as men. Among 584 women between the ages of 20 and 64 the unmarried amounted to 150 (26%). This seemed to us to be a high proportion, and we were surprised to discover

*The actual D.U./G.U. ratios were in males 1,559/137 for out-patients as against 638/94 for in-patients; and in females 454/86 for out-patients as against 112/41 for in-patients. Excluded from the calculation of duodenal-ulcer/gastric-ulcer ratios were 36 patients with small ulcer, 49 with combined gastric and duodenal ulcer, and 52 in whom the site was not stated.

TABLE IV.—Social Grade of Male Patients Aged 20-64

Age	Site	Social Grade			
		I and II	III	IV	V
20-34	Gastric	2 (2.9)	20 (26.0)	7 (5.8)	11 (5.3)
		46	416	90	78
35-49	Gastric	3 (6.2)	62 (58.8)	13 (11.9)	11 (12.1)
		65	589	119	123
50-64	Gastric	6 (6.5)	40 (42.8)	15 (9.8)	8 (9.9)
		40	266	55	63

From the table are excluded 80 duodenal ulcer and 11 gastric ulcer patients whose social grade was not stated. The figures in brackets give the number of gastric ulcers expected at each age if site and social grade were independent.

that it agreed fairly closely with the proportion of unmarried women in the general population; for women aged 20-64 the 1931 Census for England and Wales gives the proportion of unmarried as 3,747,699 to 11,743,965, or 32%.

Relative Incidence of Duodenal and Gastric Ulcer in Great Britain

Nicol (1941) stated that the relative incidence of duodenal and gastric ulcers varied throughout Great Britain, and ranged from 8 to 1 in Scotland to 1 to 1 in London. He doubted whether the London figures were truly representative of the ulcer population in that area, and suggested that it was the practice in London to treat more cases of duodenal ulcer as out-patients than was usual in other cities, so producing an artificial difference in the ratio of duodenal to gastric ulcers. This was confirmed by Avery Jones and Pollak (1945), who by including out-patients found that in London duodenal ulcer was two and a half times as common as gastric ulcer. Nevertheless there is still a gross discrepancy with our finding in the West of Scotland that duodenal ulcer is about eight times as common as gastric ulcer.

Figures are not available giving the relative incidence of duodenal and gastric ulcers in the general population, but during the war many reports were made on peptic ulcer in the Services, and in these the D.U./G.U. ratio varied from 4.0 to 1 (Rook, 1943) to 8.7 to 1 (Morris, 1940). By taking only males under 45 years, and so making their series comparable with the Service patients, Avery Jones and Pollak made the ratio of duodenal to gastric ulcer 5.5 to 1. It would therefore appear that their experience with this age group may be taken as representative. However, when the same group of patients is considered in our series the D.U./G.U. ratio becomes 13.2 to 1. Consequently it must be concluded that the relative preponderance of duodenal ulcer over gastric ulcer is much greater in hospital practice in Scotland than in London. Whether this difference is due to an absolute increase in duodenal ulcer or a deficiency of gastric ulcers remains to be established.

Summary

A two-year survey of the peptic ulcer patients attending a Glasgow hospital is reported. The survey included both in-patients and out-patients. The chief findings were:

1. The overall sex ratio was 3.5 males to 1 female.
2. The overall site ratio was 7.7 duodenal ulcers to 1 gastric (9.5 to 1 for males and 4.4 to 1 for females). There was no evidence that the ratio of duodenal to gastric ulcer was influenced in males by social status or in females by marital status.
3. Patients with duodenal ulcer were notably younger than patients with gastric ulcer, and the age at onset of symptoms was also lower in duodenal ulcer.
4. The complications of ulcer which the patients had suffered were recorded. Attention is drawn to the relative rarity of perforation in duodenal ulcer in women.
5. In-patients differed from out-patients in respect of sex, age, site of ulcer, and complications. This is attributed to the

fact that in-patients were a selected group comprising chief patients who had suffered one or more complications.

6. The ratio of duodenal to gastric ulcer appears to be much higher in Scotland than in London. This finding is discussed.

We wish to express our gratitude to Professor Illingworth, who proposed this survey, to the physicians, surgeons, and radiologists of the Western Infirmary for their ready co-operation, and to M. S. G. Murray, Miss C. M. Atkinson, and Miss M. K. Chisholm for much secretarial help, loyally and efficiently given.

THE DIET, HAEMOGLOBIN VALUES, AND BLOOD PRESSURES OF OLYMPIC ATHLETES

BY

W. T. C. BERRY, M.A., M.B. J. B. BEVERIDGE
 E. R. BRANSBY, Ph.D. A. K. CHALMERS, B.Sc.
 B. M. NEEDHAM, B.Sc. H. E. MAGEE, M.B., D.Sc.
 H. S. TOWNSEND, M.B.

Ministry of Health

AND

C. G. DAUBNEY, M.Sc., F.R.I.C.

Department of the Government Chemist

At a recent meeting of the Nutrition Society on the nutrition of athletes it was made clear that there were but few scientific data relating to the nutrition and physiology of athletes. The gathering of many athletes in London for the Olympic Games gave an opportunity for the study of certain aspects of their physiology—namely, the food consumption, haemoglobin levels, and blood pressures.

Food Consumption

Most of the athletes were housed and fed at the R.A.F. camp at Uxbridge, others being accommodated at a number of smaller centres. Different nationalities occupied different blocks, a dining-room in each block being reserved for the athletes. Food was prepared in three separate kitchens at the main camp. There was also one central cafeteria for snacks and light meals where athletes could entertain their guests. If any athletes were unable to come to camp for a meal they were provided with sandwiches; occasionally they had meals in outside restaurants. These various arrangements made the collection of food records somewhat complicated. Many of the athletes were under considerable mental tension before their contests, and it was therefore essential to exercise a good deal of tact in obtaining the food data. A further complication was that national dishes were in many cases provided and the nutrient values of these were not available in the customary tables of food composition.

The method of survey was as follows. On the Monday of each week the athletes chosen for study were interviewed and their co-operation enlisted. The study of each athlete lasted from Tuesday (breakfast) until Friday (supper)—that is, for four days. The athletes collected their food on the cafeteria system; a dietitian followed and was served with duplicates of the meal. At the end

each meal the food left by the athletes was collected. To duplicate meals and the left-overs thus obtained were put separately into Kilner jars for eventual chemical analysis. Each meal the athlete told the dietitian what extras had been eaten since the previous meal, replicas of which were then obtained either from the cafeteria or from the teams' supplies. The Kilner jars were kept in cold storage, and the end of four days were sent to the Laboratory of the Government Chemist for chemical analysis. The collection of the food samples was done by three of us (J.B.B., K.C., B.M.N.). In addition, Miss Lowden, of the Ministry of Food, collected four sets of diets by the same method from a smaller centre, the results of which have been included here.

Chemical Analysis of the Diets

The chemical analyses were made in the Department of Government Chemist under the direction of one of us (G.D.). The mixtures of foods received for analysis consisted of duplicates, as near as could be judged, of the diets of the athletes as served at the camp canteens over

McCance and Widdowson (1946) and of Chatfield and Adams (1940) were used to calculate the nutrient values of any foods not obtainable for chemical analysis.

Results of Diet Studies

The results are shown in Table I. The protein intakes ranged from 65 to 231 g. a day, averaging 139 g. daily. Only three athletes had less than 100 g. daily. The high intakes were in the main due to large consumptions of meat, eggs, and milk. The intake of fat ranged from 92 to 223 g. a day, and averaged 137 g. daily. The carbohydrate intakes were from 128 to 572 g. a day, with an average of 390 g. daily. The proportions of glucose, sucrose, and starch eaten varied widely, some athletes taking liberal helpings of sugar in their tea, others taking glucose, while others took but small amounts of sugar and no glucose. The calorie intakes ranged from 2,113 to 4,739 daily, with an average of 3,350 daily. There was no consistent difference in the calorie intakes of different types of athletes—e.g., sprinter or long-distance runner. This aspect was further examined

period of (usually) four days, together with the actual "savings" of meals.

To secure a representative sample each Kilner jar was weighed as received, the contents tipped into a large aluminium container, and the jar weighed empty. Any pebbles, stones, and similar material of no food value were removed and weighed to obtain the amount of the edible material supplied and of the leavings. These leavings were analysed separately. The whole of the food was then introduced in portions into a large hand-operated mincer to produce a finely ground product. After thorough mixing an aliquot was transferred to a Waring blender to produce homogenized product for analysis. If the liquid in the mixed food was not sufficient for the blender to operate properly a known weight of water was added to bring the mixture to a suitable consistency.

The determination of moisture, ash, fat, and nitrogen was carried out as described by Bransby *et al.* (1948). The carbohydrate values were obtained "by difference"—that is, the amount remaining after subtraction of the moisture, protein, and ash. The factor 6.25 was used to calculate the protein content from the nitrogen values found by analysis. The factors 4, 9, and 4 were employed to calculate the calorie value of the diets from the respective protein, fat, and carbohydrate contents. The food tables of

by considering the energy available for the normal everyday activities and athletic exercise, after making allowance for the basal metabolism. Thus for each athlete the requirement for basal metabolism and the allowance for specific dynamic action—namely, 10% of the calories provided by the food—were deducted from the total calorie intakes. The remainder, called for brevity "spare" calories, were compared, according to the type of athlete. Again, there was no consistent variation of these "spare" calories with the type of event. The "spare" calories per kg. of body weight were then calculated for each athlete (last column, Table I). The results for four nationalities are set out, according to event, in Table II. The data for the Canadians

and Chinese suggest that more "spare" calories per kg. of body weight were required for long-distance than for short-

distance events, but this was not substantiated by the data for the Belgians, British, and Luxemburgers.

Ascorbic Acid.—Estimations of the ascorbic acid intakes were made for seven athletes. Duplicate portions of all foods containing ascorbic acid were collected from the kitchens and were analysed by Dr. C. W. Herd. The intakes (mg.) per day were: British, 71, 80; Luxemburger, 45; Belgian, 81; Canadian, 41; Chinese, 43; Jamaican, 98. Orange juice contributed largely to the last value.

Food Habits

Twenty athletes were interviewed concerning their normal food habits and their food habits during training and on the day of the race or event. Most of them stated that they were always in training and that consequently their diet underwent little change when they were getting ready for a race. The majority stressed the value of generous helpings of meat, eggs, and milk. Thus one marathon runner normally has two or three eggs and 1-1½ lb. (453-680 g.) of steak daily, and a sprinter two eggs and 1 lb. of steak daily. There were, however, a number of interesting variations as the day of the race approached. Two short-distance runners tend to eat less, a marathon runner to cut down on milk, and a javelin-thrower to cut out afternoon snacks and drink more milk. A middle-distance runner has the same food but larger helpings, and a short-distance runner tries to have more eggs, milk, and meat. Another middle-distance runner has a normal diet throughout training, but on the day preceding the race eats more than usual. The athletes thus did not behave uniformly, but appeared to fall into three groups: those who did not vary their normal habits throughout training, those who tended to eat less, and those who tended to eat more.

On the day of the race food habits often changed considerably. The majority have a normal breakfast, but again there are interesting variations. One short-distance runner has additional eggs and bacon; two others omit breakfast, and another has a broiled steak the night before the race and poached eggs for breakfast. A middle-distance runner and a marathon runner have no breakfast. In practically all cases a lightly cooked meal is eaten three to four hours before the event. Most short- or middle-distance runners have a light snack, the favourite appearing to be poached eggs on toast; but two short-distance runners each have 2 lb. (900 g.) of steak, one additionally having milk, the other chocolate, three-quarters of an hour before the race. Each of the three marathon runners interviewed has a good meal of steak or eggs and bacon about four hours before the race; a 10,000-metre runner has a normal breakfast and nothing within four hours of the race; a wrestler has nothing between 6 o'clock the previous evening and the weigh-in in the morning, but about three hours before the event has a hearty meal of steak, potatoes, and cakes. A javelin-thrower has a normal breakfast and a light snack four hours before the event, and a high-jumper makes no variations at all from his normal diet.

Some athletes specially mentioned sugar, glucose, and salt. Two short-distance runners and a javelin-thrower make a point of taking a lot of sugar in their drinks before the race; a short-distance runner and a marathon runner have glucose every morning; and middle- and long-distance runners have glucose on the day of the race. Three short-distance runners make a point of taking plenty of salt in their food, and two middle-distance runners take salt regularly when in strict training. Two short-distance runners take synthetic vitamin B₁ tablets daily, and a jumper takes preparations containing vitamins A, B, C, and D. Most of the athletes avoid taking much fat or fatty foods before the event, as it is considered indigestible.

Haemoglobin Levels

Blood samples were obtained from 147 men from 18 countries. Their ages ranged from 16 to 47 years, and they competed in a wide variety of events. Blood was taken from the finger, the subject sitting after normal non-strenuous activity. The alkaline haematin method was used with a Medical Research Council Grey Wedge photometer, calibrated against Gibson Harrison standard. The same person (W.T.C.B.) examined all the bloods. Pipettes were tested and corrections made, where necessary beforehand.

The mean haemoglobin level of the 147 men was 16 g. per 100 ml., with a range of from 13.7 to 18.6 g. a standard deviation of 1.01 g. The mean level for 93 men from temperate countries was identical with that of 54 men from warm or tropical countries—namely, 16 g.

The haemoglobin levels of 35 men competing in events involving a high oxygen debt—short-distance runners, swimmers, cyclists, and oarsmen—averaged 15.9 g., which is not significantly different from the grand average. Six divisions into events demanding great strength, great endurance, and skill rather than endurance gave averages 15.9 g., 15.7 g., and 16.2 g. respectively. None of the differences between these is significant.

Blood Pressures

Readings were taken with the subject seated, after normal non-strenuous occupation. An ordinary mercury column and-cuff sphygmomanometer was used. The diastolic pressure was read at the beginning of the fourth phase. Readings were taken either by one of us (H.S.T.) or six instances by the doctor to the team.

Values for the whole group, and for men from temperate and warm countries, are shown in Table III. The

TABLE III.—Blood Pressures of Olympic Athletes According to Climate

Group	No. of Subjects	Mean Systolic mm. Hg	S.D.	Range	Mean Diastolic mm. Hg	S.D.	Range
Temperate countries	111	121.2	13.2	100-160	76.0	8.2	60-85
Warm countries	90	116.6	13.1	90-150	79.1	7.7	65-85
Whole	201	119.1	13.1	90-154	77.4	8.1	60-85

TABLE IV.—Blood Pressures of Olympic Athletes According to Body Weight

Group	No.	Systolic Pressure mm. Hg	Diastolic Pressure mm. Hg
Temperate countries:			
Less than 140 lb. (63.6 kg.)	11	112.8	68.1
140-164 lb. (63.6-74.5 kg.)	52	120.1	75.6
165-189 lb. (75.0-85.9 kg.)	33	121.2	76.8
190 lb. (86.3 kg.) or more	15	130.8	81.2
Warm countries:			
Less than 140 lb. (63.6 kg.)	23	114.1	77.1
140-164 lb. (63.6-74.5 kg.)	44	116.2	79.1
165-189 lb. (75.0-85.9 kg.)	16	117.4	80.1
190 lb. (86.3 kg.) or more	7	126.3	84.0

TABLE V.—Blood Pressures of Olympic Athletes According to Age

Group	No.	Average Age	Systolic Pressure mm. Hg	Diastolic Pressure mm. Hg
Temperate countries:				
Under 25 years	49	21.5	120.0	75.8
25-29 years	31	26.6	124.2	74.9
30 years or more	31	33.7	119.9	77.3
Warm countries:				
Under 25 years	37	21.7	117.0	78.2
25-29 years	29	26.6	116.2	79.0
30 years or more	24	33.4	116.6	80.8

group from temperate countries had a significantly higher systolic and lower diastolic pressure than the group from warm countries.

The average systolic and diastolic pressures showed a trend of increase with increasing weight (Table IV). Table V shows mean pressures according to age. While systolic pressure shows no consistent trend, diastolic pressure tends to increase with increasing age. Classification according to type of athletic event did not reveal any significant differences in blood pressures.

Discussion

Food.—From a study of the diets of Olympic athletes in Berlin in 1936 Schenk (1936) reported that the average caloric intake of the competitors was 7,300 a day—that is, an amount vastly in excess of the highest value found in his study. The difference between them was probably due to the difference in the method of survey, the Berlin investigation relating to the foods entering the camps, the present investigation to the foods actually eaten. The average caloric intake of the 28 athletes (3,350) is about the average need of a man engaged on light work, and thus confirms the view put forward by Abrahams at the meeting of the Nutrition Society that the energy requirement of athletes is not as great as is commonly supposed. There is, however, the possibility that the food eaten during the survey period was less than that normally eaten, as the members of some teams may have been unaccustomed to the foods and meals provided. Moreover, the period of survey—namely, four days—was short, though the results are fairly consistent.

There is a good deal of variation in food habits during training, but athletes in general seem to attach importance to liberal amounts of the animal protein foods in their diets. It is not possible, however, to say whether this preference is due to special value being attached to protein *per se* or to the foods themselves which contain animal protein—namely, milk, eggs, and meat. Some athletes take liberal amounts of the easily assimilated carbohydrates—namely, glucose and sucrose—but fat did not seem to be popular, especially near the time of the event, as it is considered to be indigestible. On the day of the race the short- and middle-distance runners mostly favour a snack or light meal a few hours before the race, but the marathon runners prefer a more substantial meal. There were, however, a number of notable exceptions. Vegetables are generally avoided near the race because they cause flatulence.

Haemoglobin Levels.—A wide range of mean haemoglobin values has been reported for different groups of healthy men. In 71 studies available to us from many countries 8 average values of 16 g. or over were reported, and 11 of 15 g. or less. The remaining 52 means lay between 15 and 16 g. Differences must have existed between one group and another in respect of food habits, indulgence in tobacco, and in the amount of exercise taken, and these may account for some of the differences found or these variations, which occur even between different groups in the same country. Most of the subjects of the present study lived on a diet which provided an abundance of the factors needed for blood formation; on the other hand they smoked but little, so that the increase in haemoglobin level associated with tobacco-smoking (Wintrobe, 1942) would presumably not occur. The effect, if any, of exercise upon haemoglobin level is not known for certain. Adcock *et al.* (1949) have shown that, in comparable groups of men, those engaged in active occupations had lower average haemoglobin values than sedentary workers, and the Medical Research Council's (1945) survey also gives lower values for the more active occupations. It will be noted, however, that the most active group of all the subjects of the present investigation, the short-distance

competitors and oarsmen, had a mean level which was not significantly different from the grand average.

The subjects of the present study represent man at his optimum, and it is of interest that the mean of 16 g. was found in men from temperate and warm climates alike. The standard deviation of 1 g. and the wide range which we found show, however, that wide variations from this mean are compatible with physical perfection, for obviously none of our subjects would have represented his country had his performance been physiologically impaired.

Blood Pressures.—Treadgold (1933), in reporting on the pressures of healthy R.A.F. personnel, gives systolic means from 122 to 125 mm. in healthy men of the age range in this study, and diastolic means of from 75 to 79 mm. Symonds (1923), in America, gives systolic means of from 123.5 to 126.4 and diastolic means of 79.5 to 83.3. Robinson and Brucer's (1939) life-assurance figures for Americans show an average of 121 mm. systolic and 74 mm. diastolic, but the systolic pressure is between 118 and 119.25 for the ages with which we deal. The mean pressures of the group from temperate countries are therefore within the range of average values reported in health, a point of interest in view of the tension which prevails at the time of a world athletic contest. It may be noted that the bounding pulse, popularly held to be typical of the athlete, was not common.

Published figures (Donnison, 1929; Chamberlain, 1911; Kilborn, 1926) for the mean systolic and diastolic pressures for different peoples living in warm climates differ markedly, some being well above and some well below European means. The group of men in this study are of several races, and the number from any one nation is too small for a comparison with the European means.

Symonds (1923) showed that both systolic and diastolic pressures rose as the weight-height ratio increased. In the present study the subjects were grouped according to weight, and both systolic and diastolic pressures tended to increase with increasing body weight. There is nothing noteworthy about the relation between age and blood pressures shown in this study, especially in view of the fact that subjects with high pressures may tend to drop out or be weeded out of world athletics as they grow older.

Summary

A study was made of the food consumption, haemoglobin levels, and blood pressures of a number of competitors in the Olympic Games held in London in the summer of 1948.

The average daily intakes of 28 male competitors were 139 g. protein, 137 g. fat, 390 g. carbohydrate, and 3,350 calories. Neither the total caloric intake nor the "spare" calories—that is, the total calories less those required for basal metabolism and specific dynamic action—per kg. of body weight varied consistently with the type of event.

The food habits of the athletes varied considerably during training. The majority stressed the value of generous helpings of meat, eggs, and milk. Some took glucose or vitamin preparations or large helpings of salt. On the day of the race the usual practice among short- and middle-distance runners was to take a light meal, and the marathon runners a more substantial meal, three to four hours before the event.

Haemoglobin values were obtained for 147 men, the average being 16 g. per 100 ml. There was no difference between the average values for men from temperate and tropical countries, or according to the type of event.

Systolic and diastolic blood pressures were taken on 201 men, the average values being 119.1 and 77.4 mm. Hg respectively. Men from temperate countries had a higher average systolic and a lower average diastolic pressure than men from warm or tropical countries. Both diastolic and systolic pressures tended to increase with increasing body weight, and there was a tendency for diastolic pressure to increase with age.

We wish to express our appreciation of the facilities placed at our disposal by Messrs. John Gardner (London), Ltd., the caterers at the Olympic Camp at Uxbridge, and other help received from members of their staff, and particularly Miss Blundell. We are grateful to the doctors and managers of the teams for their co-operation and assistance, and particularly to Dr. A. Istamboul for his help and for the data he provided. The study could not have been made without the good will of the athletes, and we wish to express our thanks to them for their co-operation.

is obliged to provide for the entire secretion of fluid. As the result of this a chronic oedema arises, which gradually leads to degeneration and atrophy of the epithelium." One may suggest an analogous explanation for the secondary changes in the oral mucosa when they arise in cases of chronic xerostomia of any nature. According to Sjögren's investigations it seems clear that the dryness of the mouth and eyes is preceded by changes (microscopical) in the salivary and lacrimal glands.

Non-ocular features of the disease (Weber, 1945), in addition to the changes in the salivary glands and mouth may include dryness in the nose, pharynx, and larynx; secondary dysphagia (Plummer-Vinson syndrome); secondary cough (from dryness of mouth and pharynx); achlorhydria; dryness of skin; dryness and atrophic change in the vagina; almost complete alopecia; accelerated blood-sedimentation rate; hypochromic anaemia; low blood pressure; low blood sugar; low blood calcium; Raynaud-like blueness of hands and feet; telangiectasis on lips and tips of fingers; telangiectatic and pigmentary scleroderma-like changes in the legs (Sheldon, 1938-9); and delusional mental symptoms and occasional epileptic fits (Sheldon 1938-9). But some of these features may possibly be regarded as superadded conditions, not directly connected with Sjögren's disease. However, in regard to the curious pigmentary scleroderma-like dermatosis in Sheldon's case one of us (Weber, 1945) has heard of another case of Sjögren's disease with similar leg pigmentation.

In the present case the unusual feature is the occurrence of dryness of the bronchial mucosa with some radiological basal pulmonary shadowing of uncertain nature, which may perhaps be interpreted as an infected (granulomatous) atelectasis due to breakdown of the natural defence owing to the dry bronchial mucosa.

SJÖGREN'S DISEASE, WITH DRYNESS OF THE BRONCHIAL MUCOSA AND UNCERTAIN LUNG LESION

BY

PHILIP ELLMAN, M.D., F.R.C.P.

Consulting Physician L.C.C. Hospital Service
and Dorking County Hospital

AND

F. PARKES WEBER, M.D., F.R.C.P.

Consulting Diagnostician to the German Hospital

Henrik Sjögren (1933, 1935, 1938, 1946), of Jönköping, by the careful study of cases of kerato-conjunctivitis sicca, has succeeded in establishing the existence of a syndrome, or rather a disease, which in its complete form includes kerato-conjunctivitis sicca, xerostomia, rhinitis sicca, pharyngitis sicca, and laryngitis sicca, but the disease is far more often incomplete. The eye lesion need not be the presenting condition, and patients may first seek medical advice because of enlargement of salivary glands or because of xerostomia.

The chronic inflammatory changes in the parotid glands, usually without suppuration but with recurrent exacerbations, tend to produce permanent enlargement, sclerosis, or atrophy in irregular combination. Analogous changes occur in the other salivary glands and in the oral mucosal glands and also in the lacrimal glands, though usually without obvious clinical enlargement. It seems certain that many cases have been labelled as Mikulicz's disease or Mikulicz's syndrome. The skin, especially the sweat glands, and the stomach (acid-producing glands) may be involved in some cases. The clinical onset, often more pronounced on one side than the other, is intermittent and insidious. The patients are mostly middle-aged women. Clinical accompaniments may include accelerated blood-sedimentation rate, alterations in the blood count, in the body temperature, and in the blood-sugar curve, and not rarely arthritic symptoms (rheumatoid arthritis).

In regard to the eye condition Sjögren concluded: "The morbid changes appear to find their simplest explanation in the fact that, owing to intense diminution or complete abolition of the lacrimal secretion, the conjunctiva itself

The patient is a delicately built woman of medium height aged 34 on Nov. 13, 1948, thin, but apparently not losing weight. Her father died at 57 of heart failure; he suffered from bronchitis. Her mother died at 69 of "sugar diabetes." The parents had eight children, of which the patient is the seventh; all the others are said to be living and healthy. The patient herself has always been thin and delicate-looking, and since the age of 13 has been subject to short Raynaud-like attacks in the fingers—the tips turn white and then blue—relieved by putting the hands into hot water. She had measles at 17 and scarlet fever at 21. While still in the fever hospital after the scarlet fever she developed temporary swellings on both sides of the face, which were considered possibly mumps. About 1940 she noticed a peculiar dryness of the lips and mouth, which she did not get rid of. In January, 1942, painless cherry-sized parotid swellings developed, one on each side, and were diagnosed as Mikulicz's disease. For these she received deep x-ray treatment at the Cancer Hospital (six sittings) and they disappeared, but not the dryness of the mouth.

Menstruation, which began at 12 years of age, has remained normal. She married in February, 1939, and in December, 1943, a child (boy) was delivered by caesarean section owing to the presence of a uterine fibroid, which was removed at the same time. The boy was normal at birth and has remained healthy. After suckling him for 8½ months she developed two small painless lumps (September, 1944), one on each side, under the lower jaw. With deep x-ray treatment (six sittings) they disappeared. She received further deep x-ray treatment in February, 1946, but for the past eighteen months she has had a small painless swelling in the right sublingual region. About September, 1944, her eyes felt hot, dry, and irritable, and the doctor told her she had conjunctivitis. It cleared up, but has returned on and off ever since.

In April, 1946, she suffered from "dry pleurisy," first on one side and then on the other. For this she was in bed for three weeks only, but never got rid of the dry cough and since the

Case Report

as never felt quite well. Since then also the eyes have been rier, and in February, 1948, they became much worse and follicular" conjunctivitis was diagnosed.

In May, 1948, a stiff neck was followed by painful swelling of the knuckles, and pain and stiffness in the wrists, knees, feet, and left shoulder, with some fever. This polyarthrits of the rheumatoid arthritis type, for which she was referred to one of us (P. E.) by Dr. W. Edwards and treated at the Leatherhead Hospital, has now nearly subsided. Her dry cough has become much worse, and when she is talking she has to sip water frequently to relieve the dryness.

Present Condition

She complains of dryness of eyes, mouth, and throat and a ritable dry cough, much worse on talking. Sometimes she has ight difficulty in swallowing. Most of her teeth have been rtracted. By palpation with the finger and thumb a painless erry-sized swelling can be felt below the tongue to the right f the middle line. There is slight symmetrical enlargement of e thyroid gland, but no clinical evidence of thyrotoxicosis.

A blood count (Aug. 14, 1948) showed: haemoglobin, 98%; ythrocytes, 4,980,000; colour index, 0.99; leucocytes, 6,000. nother blood count (Dec. 31) gave: haemoglobin, 103%; ythrocytes, 5,700,000; colour index, 0.9; leucocytes, 7,600. olymorphs 81%, lymphocytes 18%, monocytes 1%. Urine owed nothing abnormal. Blood pressure was 120/80 mm. g. Blood Wassermann reaction was negative. Blood sedi- entation rate was not raised on June 28, 1948, when it was ; but on Sept. 26 it was 22 (normal 4 to 8). Blood calcium as 10.6 mg. per 100 ml., blood phosphorus 3.9 mg. per 100 ml.. d blood alkaline phosphatase 9 units. There has been no utum at present. There was no clinical evidence of disease f the heart, abdomen, or central nervous system. In the lungs ere is diminution of air-entry at both bases, breath sounds e tubular in type at the left base, and numerous dry crepita- ns can be heard at both bases, but are especially marked at e left base.

X-ray examination of the chest (July 11, 1947) showed dim- ined translucency in the left lower lobe, with pleural involve- ent. On Aug. 16, 1948, there was an area of consolidation in e left lower lobe, with some scattered opacities in the right wer lobe. The heart, mediastinum, and trachea were centrally aced, the left diaphragm was obscured, and the heart was rmal in shape, size, and position. A further skiagram on ov. 30, 1948, showed little appreciable change. Bronchoscopy as negative, except for dryness of bronchial mucosa; no cretion was obtained (Mr. W. P. Cleland, St. Helier Hospital, arshalton). Electrocardiogram was normal. The hands owed soft-tissue swelling of the proximal interphalangeal ints but no bony changes, nor were there any bony changes e other joints.

The following additional investigations were carried out at e Hammersmith Hospital. The sputum showed Gram-positive cci and diphtheroids on direct smear, and *Staphylococcus ireus* on culture. Fractional test meal gave normal secretion f hydrochloric acid. Urinary excretion of 17-ketosteroids and e glucose-tolerance test were normal. Schirmer's lacrimation st showed moistening along 0.5 cm. of the filter paper com- ared with 3 to 5 cm. in controls. Salivation test, consisting of llection of saliva for three minutes after chewing and swal- wing fruit, gave 0.8 ml., whereas control subjects produced o 9 ml. A heating test for sweating gave normal response. liver biopsy (performed because pulmonary sarcoidosis had en suggested) showed normal histology.

Treatment

Treatment was directed symptomatically to the dry eyes, y mouth, and dry bronchial mucosa. So far as the eyes e concerned cod-liver oil drops gave symptomatic relief. Attempts were made to increase the salivary secretion by pilo- rpine, mechohine, and physostigmine. These produced no ppreciable response as shown by the salivation test. In the pe that the changes at the base of the left lung might be roved an attempt was made to alleviate dryness of the onchial mucosa by keeping the patient for a fortnight in eam tent (Hammersmith Hospital). This had no beneficial ect on the respiratory condition and the patient thought that

the dampness aggravated the arthritis. Breathing exercises and postural drainage produced no significant result. She was given vitamin A, 150,000 units daily, empirically, as it was thought that this could not possibly do any harm and might conceivably do some good. Closure of the lacrimal ducts by local dia- thermomy was not carried out, since the eye symptoms were not the most troublesome. The patient thinks that inhalation therapy helped her at the Hammersmith Hospital.

Discussion

This case seems to be one of Sjögren's disease, which, we think, may be regarded as a lymphoid granulomatous con- dition, affecting especially the salivary and lacrimal glands and giving rise to dryness of the mouth and conjunctivae. The presence of slight rheumatoid arthritis may be regarded as a point in favour of this diagnosis. In the present instance the bronchial mucosa is specially affected, and there are pulmonary lesions of uncertain nature, probably granulomatous. Dryness of the bronchial mucosa seems as yet not to have been noted in Sjögren's disease, though its occurrence might have been expected in some cases.

The main salivary gland swellings have disappeared under deep x-ray therapy, but the dryness of the mouth and con- junctivae has increased if anything, and there is a swelling in the right sublingual region. Further treatment of the case, beyond inhalation therapy, is problematic, but we think that the lacrimal ducts should now be closed by diathermy in order to diminish the conjunctival dryness. Mikulicz's disease is a lymphoid granulomatous condition of the salivary and lacrimal glands very susceptible to x-ray treatment, and it is a question how far it can be distinguished from Sjögren's disease, to which perhaps it may be an allied condition (variant). The advisability of further deep x-ray treatment is a matter for consideration—in regard both to the sublingual nodule and to the lungs.

There is also the question of the lung condition being of sarcoid nature, but the negative liver biopsy makes this unlikely. We need not therefore consider the further ques- tion of a possible relationship between Sjögren's disease, Mikulicz's disease, and sarcoidosis. The replacement of glandular tissues in Sjögren's disease and Mikulicz's disease by a kind of lymphoid granulomatous tissue reminds one, it may be noted, of the gradual replace- ment of thyroid glandular tissue by lymphadenoid tissue in cases of so-called lymphadenoid goitre.

We are greatly indebted to Dr. J. G. Scadding for the investigations carried out at the Hammersmith Hospital. We have to thank Dr. J. N. Cunnings and Dr. S. A. Withers for the routine clinical-pathological and the x-ray examinations respectively.

The Ministry of Health states that in many hospitals and clinics the arrangements for the reception and treatment of out-patients in the past have left much to be desired. It suggests that boards and committees should have in mind the elimination of unnecessary out-patient attendances, the reduction of waiting-time to a minimum, and the maximum convenience and comfort of the out-patient. "The institution of an effective appointment system is probably the biggest single contribution that can be made to the convenience and comfort of out-patients." It adds that the resulting saving of space should make possible the replacement of unsightly and uncomfortable forms by cheap but comfortable chairs, and a canteen for out-patients is an amenity which should be provided. Particular attention should be given to the holding of treatment clinics such as physiotherapy and rehabilitation in the evening or at other times outside the normal working hours of patients, so that working time need not be lost by patients unnecessarily.

ILLNESS IN GENERAL PRACTICE

BY

JOHN PEMBERTON, M.D., M.R.C.P.

(From the Department of Medicine, University of Sheffield)

We are fortunate in this country in possessing elaborate and reliable information on the causes of mortality, but with the greater emphasis now being placed on the early diagnosis and the prevention of illness more data are required on morbidity.

This need is being partially met by the surveys of sickness carried out by the Social Survey for the Ministry of Health, whose first report appeared in 1946 (Slater, 1946). The information collected by the Social Survey is obtained by non-medical workers, and while it gives valuable information about the general incidence and trends of illness based on broad diagnostic groups it cannot be expected to provide the detailed information about illness in the community which only certification by doctors can yield. Detailed information on the causes of incapacity from sickness amongst the insured population of Scotland was published by the Department of Health for Scotland (1939), and provides a wealth of morbidity data about this population group in the year 1936-7.

The following survey was undertaken to obtain information about the types and relative frequency of illnesses which lead people to consult their general practitioner.

Scope of the Survey

Eight general practitioners living in Sheffield or its neighbourhood recorded the age, sex, and diagnosis of all the patients, panel and private, who consulted them in the course of one winter week, February 1 to 7, and one summer week, June 28 to July 4, in 1947. They also indicated whether the patient was seen in the surgery or the patient's home and which cases it was necessary to refer to a hospital or local authority clinic.

The total number of consultations was 4,656 (2,816 in the winter week and 1,840 in the summer week). Only seven of the doctors were able to carry out the summer week survey, as the eighth had left the district. Six of the practices were within the boundaries of the city of Sheffield, one was in Rotherham, and one was situated in the neighbouring mining-agricultural town of Clowne.

Of the 4,656 consultations, 3,041 (65.2%) were held in the doctor's surgery, 1,542 (33.2%) in the patient's home, and 73 patients (1.6%) sent relatives to the doctor on their behalf.

The average number of consultations carried out by each doctor was 353 in the winter week and 265 in the summer week. In 2% of the consultations the patient was referred to a hospital out-patient department, in 0.16% to an in-patient department, and in 0.2% to a local authority clinic.

Age and Sex.—Table I shows the distribution of the patients by age group and sex. The total numbers of

TABLE I.—Percentage of Patients Falling in Each Age Group, Males and Females

males and females were nearly equal, but in certain age groups one sex predominated. Females exceeded males

in the age group 15-29 mainly because of consultations for obstetrical or gynaecological conditions. Males were in excess in the age period 40-69 but not after that age.

The Illnesses

Table II shows the main causes of illness found in the two-weeks survey and their relative frequency. The

TABLE II.—Incidence of the Different Types of Illness

Illness or Group of Illnesses	Winter Week (2,907 Complaints)		Summer Week (1,907 Complaints)		Both Week (4,814 Complaints)

Miscellaneous and unclassified	189	6.5	162	8.5	351	7.3

number of diagnoses (4,814) exceeds the number of consultations (4,656) because some patients were suffering from more than one complaint.

Respiratory Disease.—The respiratory group of illness was by far the largest, accounting for 41.3% of the diagnoses in the winter week and 21% in the summer week. The frequency of the different varieties of respiratory illness is shown in Table III. In the winter week influenza

TABLE III.—Analysis of the Respiratory Illnesses

	Winter (1,201 Respiratory Illnesses)		Summer (400 Respiratory Illnesses)	
	No.	%	No.	%
Influenza	416	34.6	11	2.7
Bronchitis	386	32.0	144	36.0
Coryza	113	9.4	24	6.0
Diseases of pharynx and tonsils	78	6.5	106	26.5
Pneumonia, all forms ..	58	4.8	22	5.5
Asthma	51	4.3	29	7.3
Pulmonary tuberculosis ..	20	1.7	13	3.25
Emphysema	4	0.3	3	0.75
Other respiratory diseases	75	6.3	48	12.0

accounted for 34.6% and bronchitis for 32% of all respiratory illness. It so happened that a minor epidemic of influenza A reached its peak during this week (Stuart Harris, 1947). In the summer week bronchitis still accounted for 36% of the respiratory illness, while the percentage attributable to influenza had fallen to 2.7%. The fall in the number of influenza cases in the summer week has the effect of making the percentage incidence of the other causes of respiratory illness disproportionately high. There were, however, more cases of disease of the pharynx and tonsils in the summer week. The poliomyelitis epidemic was gaining ground at this time, and it is possible that some of these pharyngeal conditions represented abortive attacks of that disease. Taking the winter and summer weeks together, bronchitis was the commonest complaint for which medical aid was sought from the general practitioners, accounting for 11% of all the consultations.

Digestive Diseases.—These came next in frequency. In this group 68% were cases of dyspepsia of various types, excluding cancer. The other chief complaints in order

were diarrhoea and enteritis, disorders of the colon, hernia, and appendicitis.

Cardiovascular Disease.—The cardiovascular group, which was the third largest, was subdivided as follows: essential hypertension and cerebrovascular accidents, 37%; coronary disease, 14%; rheumatic heart disease, 12%; other diseases of the heart, 30%; and other diseases of the blood vessels, 7%. "Other diseases of the heart" included the rather ill-defined condition "myocarditis." Some of these cases should perhaps have been assigned to the coronary disease group.

Mental Ill-health.—Cases of mental ill-health consisted of psychoneurosis 93.6%, psychosis 6.1%, and mental deficiency 0.3%.

Obstetrics and Gynaecology.—In this group 36% were antenatal consultations, 31% gynaecological complaints, 10% menopausal disturbances, 9.4% post-natal visits, 5.4% abortions, and 5% confinements.

Chronic Rheumatism.—Under this heading, which accounted for 5.5% of the diagnoses, were included umbago, sciatica, fibrositis, rheumatoid arthritis, and osteoarthritis.

Accidents.—Of the accidents 18% were fractures, 9% strains, and 4% burns or scalds. The remaining 67% came under the heading "other accidents."

Acute Specific Fevers.—Of the 224 cases in this group 12% were measles, 9% chicken-pox, 4% whooping-cough, 3% German measles, 1% scarlet fever, and 0.9% mumps.

Preventive Medicine

No patients in this series consulted their doctors for a routine health examination or for advice on the preservation of their health. A certain amount of advice was given by the doctors concerned with regard to the prevention of further illnesses, but the only examples of purely preventive work which were recorded were the 99 antenatal consultations and 35 vaccinations. Together, these constituted 2.9% of the total consultations. No consultations came under the heading of forensic medicine.

From this survey it would seem that the most important classes of disease which the general practitioner is called upon to treat are the respiratory, digestive, cardiovascular, and psychological diseases in that order, followed by obstetric and gynaecological conditions, chronic rheumatism, and accidents.

The low incidence of psychological complaints (6.5%) was commented upon by two of the doctors participating in the survey. This may have been due partly to the fact that in the winter week the weather was very severe and may have discouraged a number of psychoneurotics from attending (although the summer figure was very little higher), and partly to the inclusion of some of these cases under other headings, such as "dyspepsia" or "rheumatism."

In amalgamating the diagnoses of a number of doctors the different criteria employed might lead to the grouping

together of conditions which are in fact distinct. The frequency with which the different practitioners diagnosed similar conditions is shown in Table IV, and their correspondence suggests that the diagnostic criteria used by the doctors concerned were similar.

Discussion

It is interesting to compare the pattern of morbidity as revealed in the present survey with a somewhat similar analysis carried out in Sheffield by Calvert Holland in 1843. He records his attempt "to ascertain the nature of the diseases prevailing amongst the working classes" in Sheffield, "from the books of the surgeons at the poor-house." His analysis of the illnesses of a random sample of 200 males whose ages ranged from 20 to 74 years is shown in Table V. No close comparison with the present

TABLE V.—*Dr. Calvert Holland's Analysis of 200 Cases of Sickness in Men Living in Sheffield in 1843*

Type of Illness	Percentage
Diseases of the air passages	30.0
Diarrhoea and dysentery	13.0
Diseases of the digestive apparatus	12.5
Rheumatism	12.5
Diseases of the nervous system	9.5
Fever	5.0
Diseases of the urinary organs	3.5
Diseases of the heart	1.5
Diseases of the skin	1.5
Debility	1.5
Miscellaneous	9.5

series is possible, as Holland's cases consisted only of adult males from the "labouring classes." Nevertheless it is interesting to note that the incidence of respiratory disease in his survey, as in the present one, heads the list—"diseases of the air passages" accounting for 30% of his series of cases, compared with 34% in the present series. The high incidence of diarrhoea and dysentery at that time compared with the present was no doubt largely due to the deficient sanitary arrangements which then prevailed. Digestive disease and rheumatism figure high in Holland's survey, as in the present one; on the other hand, cardiovascular disease was relatively unimportant. This may be attributed to the fact that only 29 of his 200 patients were over 50 years of age. He also tells us that the mean duration of life in Sheffield at that time was 24.12 years. At that time the chances of a baby living to a "cardiovascular age" were in fact not great.

The pattern of morbidity has changed over the last hundred years, but respiratory disease still dominates the picture. In this group, cases of bronchitis are numerically the most important.

Although the diagnosis of "bronchitis" is not always precise, the condition or group of conditions to which it refers is clearly of great medical and social importance as shown by this and other surveys. Thus in the report on incapacitating sickness in the insured population of Scotland it accounted for 6.57% of the total days of incapacity and was exceeded only by influenza. Gafar (1944), analysing the causes of sickness absence among 293,960 male industrial workers in the United States, found that bronchitis was responsible for 7.5% of all absences, again being exceeded only by influenza.

The distribution of cases of bronchitis in the present survey by sex and age group is shown in the accompanying Chart, where it is compared with the notifications of pulmonary tuberculosis in Sheffield in 1947 (Roberts, 1947). In adult life the sex-age morbidity pattern of the two diseases is somewhat similar. Females predominate in the first part of working life and males in the later part. Adverse occupational conditions are known to influence the incidence

TABLE IV.—*Proportion of Each Doctor's Diagnoses Falling in the Seven Main Diagnostic Groups (winter and summer combined)*

Diagnostic Group	Dr. A %	Dr. B %	Dr. C %	Dr. D %	Dr. E %	Drs. F & G %	Dr. H %	All Doctors %

* This practice was in a mining district.

of tuberculosis. It seems highly probable that occupational factors are also concerned to an important extent in the aetiology of bronchitis.

One of the general practitioners taking part in the present survey wrote: "I feel that the specialized fields of the profession have little conception of the actual work that is done by the general practitioners, and too much attention is paid to fields of medicine which the future general practitioner is rarely if ever called upon to practise."

The present survey does indeed suggest that the student who intends to become a general practitioner may spend a disproportionate amount of time in examining and studying relatively rare diseases. He would benefit from seeing more cases of minor illness than he can hope to find in a teaching hospital and from more opportunities of seeing

The following general practitioners, by their careful collection of data, made this survey possible: Drs. B. Droller, H. Droller, C. H. Foggitt, M. Jacob, R. B. Knowles, G. E. Tilsley, W. Toms, and E. Zadik. I wish to thank all of them for allowing me to use their records and for their suggestions with regard to the interpretation of the figures. The severe frosts and heavy snowfalls made the work particularly difficult during the winter week. I am indebted to Professor C. H. Stuart-Harris for helpful advice and criticism, and to Miss B. I. Richardson for valuable assistance in the analysis of the data.

Distribution of cases of bronchitis by sex and age group, compared with the notifications of pulmonary tuberculosis in Sheffield in 1947

disease in its early stages. Some experience in the treatment of the chronic sick and of infirm old people in the home would also be of value to him. Suitably staffed health centres and home visiting from these centres might in the future be used with advantage for the demonstration of such cases to the medical student. In the health centres he could also learn to appreciate the opportunities for practising preventive medicine which occur in general practice.

Summary

The 4,656 consultations undertaken by eight general practitioners in one winter and one summer week are analysed by sex, age, and diagnosis.

Bronchitis was found to be the commonest condition in summer and in winter for which medical advice was sought, accounting for 11% of all cases.

The relation between the work done in general practice and the training of medical students is briefly considered.

AFEBRILE CASES OF MELIOIDOSIS

BY

R. GREEN, M.D., D.Sc.

AND

D. S. MANKIKAR, M.B., B.S.

(From the Institute for Medical Research, Kuala Lumpur, Malaya)

Recovery from infection with *Pfeifferella whitmori* is rare, the death rate being about 95%, and cases of melioidosis with freedom from marked constitutional symptoms are rarer still. The case history of an afebrile patient observed in Malaya in September, 1941, is given below. He had localized infection with *Pf. whitmori* in a cervical gland but remained free from general symptoms. He was treated by aspiration of the gland abscess, and when this refilled he was apparently cured by treatment with sulphapyridine. His response to the drug was in keeping with the findings of investigators from 1943 onwards—of which a brief review is given. Reference is made to five other afebrile cases of melioidosis observed in South-East Asia. The *in vitro* effects on *Pf. whitmori* of newer antibiotics such as streptomycin, "polymyxin," and "chloromycetin" are also described and compared with penicillin.

Case History

A male Indian artisan aged 30 was admitted to hospital in Kuala Lumpur during September, 1941, for treatment of quartan malaria. While in hospital a swelling of one of the cervical glands was noted. This was painful and tender, but was relieved somewhat by glycerin and ichthyol dressing. After receiving quinine treatment for his malaria he had no fever on the fifth, sixth, and seventh days and was discharged at his own request. He returned to work, but one month later was readmitted to hospital because of further pain and swelling in the cervical gland, which by this time was fluctuating in the centre. He had no fever on readmission or during his six-week stay in hospital. The swelling was aspirated on the second day after readmission and thick mucoid pus was withdrawn. On culture the pus yielded a pure growth of *Pf. whitmori*.

A guinea-pig which was injected with 0.03 ml. of a peptone water culture of the patient's organism died within six hours, the animal's skin showing intense oedema, with commencing haemorrhagic necrosis at the site of inoculation. When recovered from the pericardial fluid of the dead guinea-pig and cultured on glycerin agar the organism showed some intensification of its original rugose growth. This type of growth has been shown by Nicholls (1934) to be associated with the more virulent variant of *Pf. whitmori*—in distinction to the mucoid type.

Other cultural characteristics of the patient's bacillus agreed entirely with those described by Stanton and Fletcher (1932). The patient's serum agglutinated his own strain of *Pf. whitmori* to a titre of 1 in 680. A known *Pf. whitmori* serum agglutinated the patient's strain of *Pf. whitmori* to a titre of 1 in 880. He continued to remain constitutionally well and had no fever. The leucocyte picture also remained within normal limits. His cervical gland was reaspirated eleven days after admission and *Pf. whitmori* was again isolated. This re-isolated organism was fully investigated and guinea-pigs were again inoculated; all the bacteriological findings coincided with the first aspiration. These findings, together with the rapid death of the guinea-pigs—the males showing the "Straus reaction"—left little doubt concerning the virulence of the strain of *Pf. whitmori* which was infecting the patient.

The abscess in the cervical gland remained with the skin unbroken, but it tended to refill after aspiration and to show central softening. About four weeks after readmission the abscess seemed about to burst through the skin. A third aspiration was considered, but it was decided to try a course of sulphapyridine instead. Over a period of six days the number of 0.5-g. tablets given daily by mouth was 6, 4, 0, 4, 4, and 6. Treatment being interrupted on the third day because the patient, who was feeling quite well, absented himself to attend to some private affairs.

Two days after the course of sulphapyridine treatment had been completed the swelling in the gland subsided. Attempts to reaspirate resulted in the withdrawal of a little blood-stained fluid which on culture did not show the presence of *Pf. whitmori*. A few days later the patient left the hospital.

He was lost sight of during the years following the Japanese occupation of Malaya, but in May, 1948, he was traced and interviewed. He stated that he had remained constitutionally well, and on examination no evidence of ill-health was found. The former swelling in the cervical gland had disappeared completely and there were no external signs. The only remnant of the former *Pf. whitmori* infection was some slight palpable thickening in the periglandular tissues, probably due to fibrosis.

Notes on Similar Cases

The absence of constitutional symptoms in the above case was a remarkable feature. Stanton and Fletcher (1932) cite 83 recorded cases of human infection with *Pf. whitmori* and state that "melioidosis is a very deadly disease and, of known cases, only two have recovered." Full details of these two recovered cases are then given. One is described as being "desperately ill with fever, cough, and chest pains," and the second case is recorded as having "high evening temperature and bronchopneumonia. . . . For several weeks he lay in a drowsy typhoid condition." In their first case the fever lasted for three months and in the second case for four months.

Cases of melioidosis without marked constitutional symptoms have been recorded. Peck and Zwanenburg (1947) reported the case of an Indian havidar who developed a midline abscess of the neck above the suprasternal notch from which *Pf. whitmori* was obtained in pure culture. The patient had no constitutional symptoms, fever, or glandular enlargement. His serum agglutinated the organism to a titre of 1 in 80. The leucocyte count, both total and differential, showed no unusual features. Hasle and Guyen-Duc-Khoi (1937) described the case of a Chinese with a suppurative adenitis of the neck from which *Pf. whitmori* was cultured. The patient had no general symptoms or fever. Recovery followed the formation of fistula.

Other cases of melioidosis remarkable for the absence of constitutional symptoms have occurred in Java, but the infection has been confined to superficial skin lesions. De Moor, Soekarnen, and van der Walle (1932) investigated the chronic skin lesion of the buttock and thigh of an elderly Javanese. This had been present for about

eighteen months and was painless. The skin was thickened and was beset with nodules containing pus from which *Pf. whitmori* was repeatedly isolated. Their illustrations show the absence of ulceration. The blood picture was normal and there was no fever. The patient's serum agglutinated his strain of *Pf. whitmori* to a titre of 1 in 600.

Again, Sudibyo (1938) described superficial seriginous ulcers occurring in two elderly Javanese. His illustrations show healed scarred centres of the ulcers bordered by raised nodular spreading edges. Sudibyo was able to isolate *Pf. whitmori* in practically pure culture from all over the lesions, and found that serum agglutination tests against the patients' organisms were positive at titres of 1 in 400 and 1 in 800. His two patients had no loss of appetite, no emaciation, and no fever.

Treatment of Melioidosis with Sulphonamides

The majority of the cases of melioidosis occurring in South-East Asia have been investigated during the two decades preceding the Japanese occupation from 1941 to 1945, but sulphonamide compounds were available only towards the end of the second decade. Again, melioidosis is seldom diagnosed at the bedside; more often diagnosis is made in the laboratory or post-mortem room, although Stanton and Fletcher (1932) estimate that 200 cases occur each year in Malaya. Thus the factors cited above would account for the scarcity of literature on cases and their treatment with sulphonamides.

Records of treatment of melioidosis with sulphonamides begin with those of Grant and Barwell (1943) and of Mayer and Finlayson (1944), and sulphadiazine treatment is suggested by *in vitro* tests carried out by Mirick and colleagues (1946); but the clinical response to sulphonamides is more extensively investigated in an admirable paper by Harries and co-workers (1948), who conclude that the most effective treatment for the disease is 2 g. of sulphamezathine four-hourly together with local penicillin treatment, where this is possible, combined with autogenous vaccine therapy.

These findings and our case of the Indian artisan described above, who responded in 1941 to sulphapyridine treatment by reduction of his abscess and disappearance of *Pf. whitmori* from the pus, prompted us to investigate further the *in vitro* effects of the sulphonamide compounds on strains of *Pf. whitmori*, but unfortunately all our Malayan strains were lost during the Japanese occupation. Also, this investigation had to be postponed until recently, and the only strain of *Pf. whitmori* available was one isolated by Major Harries in Burma and received by courtesy of the Bland-Sutton Institute for Pathology through Dr. F. R. Selbie and Dr. R. Lewthwaite. The response of this strain to *in vitro* tests against various sulphonamide compounds is shown in the accompanying table. Fleming's "gutter technique" as described by Mackie and McCartney (1946) was used.

Drug 1 in 5,000	Inhibition Zone in mm. Occurring with Dilutions of the Bacterial Inoculum		
	1 in 10	1 in 100	1 in 500
Sulphanilamide ..	Nil	Nil	Nil
Sulphapyridine	2
Sulphathiazole	11	18
Soluthiazole	Nil	12
Sulphamezathine	12	Nil
Sulphadiazine ..	10	12	17

Allowing for possible differences in the diffusibility of the drugs within the agar medium, these *in vitro* results suggest the further clinical use of sulphathiazole or the somewhat less toxic sulphadiazine in cases of melioidosis. (Mirick *et al.* (1946), when using 15 µg. per ml. of sulphadiazine,

observed complete inhibition of growth in *Pf. whitmori* broth cultures.)

Effect of Antibiotics on *Pf. Whitmori*

Harries *et al.* (1948), in addition to using suphamezathine for melioidosis, treated a lung cavity locally by direct injection of 6 ml. of saline containing 300,000 units of penicillin (i.e., 50,000 units per ml.), having found previously by *in vitro* experiments that at least 650 units of penicillin per ml. were necessary to inhibit the growth of *Pf. whitmori*. Miller and co-workers (1948) state that penicillin at concentrations of 1,000 units per ml. has no immediate effect on *Pf. whitmori*, and they use penicillin in such concentrations for three hours at 37° C. to get rid of unwanted organisms when culturing material for isolation of *Pf. whitmori*.

The use of penicillin in melioidosis is thus confined to local treatment, using concentrations many times higher than could be obtained in the blood stream. Some newer antibiotics such as chloromycetin, streptomycin, and polymyxin, however, have a wide range of activity on Gram-negative organisms, and two are known to be capable of attaining a fairly high concentration in the blood stream; for example, chloromycetin can be initiated at 40 to 80 µg. per ml. and maintained at 20 µg. per ml. when given by mouth (Woodward *et al.*, 1948), and streptomycin, by injection, between 10 and 20 µg. per ml. (Merck, 1947). We therefore considered it of some importance to undertake *in vitro* tests with these newer antibiotics against *Pf. whitmori*.

There is considerable literature on streptomycin and its properties, but less information about chloromycetin and polymyxin. We therefore give a few notes.

Chloromycetin, together with its production, purification, and antibacterial effects, both *in vitro* and in experimental animals, is fully described by Smith and co-workers (1948); the first general announcement on this antibiotic was made by Ehrlich and his colleagues (1947). This latter paper was summarized in a leading article in the *British Medical Journal* of Aug. 28, 1948 (p. 428). Chloromycetin is an antibiotic substance obtained during the growth in culture of a variety of *Streptomyces* isolated from soil in Venezuela. An identical substance has been obtained from a variety isolated from compost in Illinois (Carter *et al.*, 1948).

As an antibiotic, chloromycetin is unique in so far as it contains both nitrogen and non-ionic chlorine and in being well absorbed when taken by mouth. It is a crystalline substance and is comparatively stable under conditions of widely varying temperature and pH. (We have found no loss of potency in chloromycetin-saline solutions kept in the refrigerator for three months.) It also has a low degree of toxicity in experimental animals.

Chloromycetin inhibits the growth of rickettsiae and of various Gram-negative organisms, including *Brucella*, *Bacterium coli*, *Shigella paradysenteriae*, and Friedländer's bacillus, the last two being conveniently used as test organisms. We have found it markedly inhibitive *in vitro* to 15 Malayan strains of *Salmonella typhi*, to the "Inaba" and "Ogawa" strains of *Vibrio cholerae*, and to *Haemophilus influenzae* (a Malayan penicillin-insensitive strain), using concentrations of chloromycetin obtainable in the blood when given by mouth—that is, 40 to 60 µg. per ml. (Supplies of chloromycetin for such tests were received by courtesy of Dr. J. E. Smadel, who also provided samples of polymyxin, these two antibiotics being at present produced in experimental quantities by Parke, Davis and Co. and Lederle Laboratories respectively.)

Polymyxin is an antibiotic elaborated during the fermentation of various media by certain strains of *Bacillus*

polymyxa (Benedict and Langlykke, 1947; Stansly and colleagues, 1947). It is said to inhibit a wide variety of Gram-negative and Gram-positive bacteria. *Brucella* and *Bact. coli* are used as test organisms in assaying the amount of polymyxin in solutions. This antibiotic appears to be basic polypeptide (Florey, 1948—personal communication) and we have found that it inhibits Malayan strains of *Salm. typhi* but is less active against *Salm. paratyphi* and *Salm. paratyphi* B when used in the same relative small concentrations (1 to 5 µg. per ml.).

The technique of testing was the ring-cup method, varying concentrations of the four antibiotics being placed in glass cylinders 15 mm. in diameter sealed on to the surface of culture plates seeded with *Pf. whitmori*. The results of repeated tests were as follows: streptomycin and polymyxin in concentrations up to 1,400 µg. per ml. failed to inhibit the growth of *Pf. whitmori*; penicillin up to 700 units (525 µg.) per ml. showed a maximum inhibition zone of 28 mm.* Chloromycetin, however, in concentrations clinically obtainable in the blood (60 µg. per ml.) gave an inhibition ring of 24 mm. Similar amounts of chloromycetin tested against 15 Malayan strains of *Salm. typhi* gave inhibition zones of 29 to 31 mm.

It is concluded that in cases of melioidosis chloromycetin should be of some benefit when used alone or combined with one of the sulphonamide compounds—sulphamezathine, sulphathiazole, or sulphadiazine.

Comment

It was of particular interest to note the inhibitory effect on *Pf. whitmori* of chloromycetin, which is produced by one species of streptomyces, as against the complete lack of effect from streptomycin, which is elaborated by another, i.e., *Streptomyces griseus*. But the streptomyces, which are likely to receive further attention as a source of antibiotics, present puzzling features; and Carter *et al.* (1948) have pointed out that the two varieties of streptomyces of wide differing origin (Venezuela and Illinois) which produce the lowly toxic chloromycetin are very closely related *Streptomyces lavendulae*, from which the more toxic streptothricin is obtained.

The complexity of this subject, however, has been stressed by Waksman (1947), who mentions the widely differing chemical nature of antibiotic substances—for example lipid-like bodies (pyocyanase), pigments (pyocyanin), polypeptides (gramicidin), sulphur-bearing compounds (penicillin), and quinones and organic bases (streptomycin)—that is, they have no resemblance except for their general origin.

Summary

The case history of a patient with melioidosis is given. He remained afebrile throughout weeks of observation. His gluteal abscess resolved rapidly under treatment with sulphapyridine and during the subsequent six years he had no recurrence.

Sulphamezathine, sulphathiazole, and sulphadiazine have also been used for treating melioidosis (abscesses in bone, skin and lung). Sulphadiazine is one of the less toxic compounds and it showed relatively a more marked inhibition of *Pf. whitmori* in a series of *in vitro* tests.

The antibiotics streptomycin and polymyxin were found to have no inhibitory effect on *Pf. whitmori*. Penicillin, except at very high concentrations unobtainable in the blood stream, also had no effect.

Chloromycetin, a new antibiotic obtained from a streptomyces, inhibited the growth of *Pf. whitmori* at concentrations obtainable in the blood when the antibiotic is given by mouth, and in clinical use, either alone or in combination with sulphonamides is therefore suggested.

*But only 2.5 units of penicillin per ml. are obtainable in the blood after an intramuscular injection of 250,000 units (Dyke, 1947).

Medical Memoranda

A Case of Charcot's Disease of the Cervical Spine

The following case of Charcot's joint disease of the cervical spine was recently under treatment at the C.M.S. Hospital, Old Cairo.

CASE HISTORY

The patient, an Egyptian, first came to the hospital in 1944 complaining of difficulty in walking. A Kahn test of cerebrospinal fluid blood was negative, but the C.S.F. contained 70 mg. of albumin per 100 ml. and 76 cells per c.mm., and clinically the case appeared to be one of tabes dorsalis, a rare disease in Egypt. This diagnosis is confirmed by Colonel Spillane, neurological specialist, who kindly examined him.

During the next year the patient had almost continuous treatment with N.A.B. and bismuth and improved considerably until he became able to walk two to three miles without undue fatigue. He remained ill until April 1947, when he began to feel "pins and needles" in the right arm and noticed some wasting of the muscles of his right hand; there was also clicking in the neck on forward and backward movement of the head. He did not suffer any serious disability, however, and continued his work as a clerk until October, 1947, when he quite suddenly had an attack of retention of urine, which had to be relieved by catheter. From this time onwards he had difficulty in micturition on and off, and gradual loss of power in the right arm and hand until Feb. 6, 1948, when he suddenly became unable to raise the arms at the shoulders or to flex them at the elbows, and there was a burning pain in the region of the right shoulder, made worse by bending the head backwards. He had also noticed girdle pains.

On Feb. 13 he was admitted to hospital. On examination he was found to be a thin, ill-looking man, aged 55. He was alert mentally, answered questions intelligently, and his speech was normal. He gave a history of having had syphilis at the age of 18, and stated that Kahn test on the blood serum, done a few weeks previously, had proved mildly positive. He held his head somewhat flexed. Flexion and extension of the neck were fairly free, but there was marked clicking on bending the head backwards, and this movement caused severe pain to radiate down the right arm. Examination revealed the following signs:

A left internal squint, stated by the patient to have been present since he was 18 years of age. Very small regular pupils, inactive to light and reacting sluggishly to accommodation. The cranial nerves, apart from the 6th, were normal. There was complete loss of power of abduction of the arms at the shoulders and of flexion at the right

elbow, but some weak flexion was possible at the left elbow. Dorsiflexion of both wrists was very weak. There was marked wasting of both deltoid and biceps muscles and of the intrinsic muscles of both hands. In contrast to this weakness of flexion, extension at the elbows was quite strong. In the lower limbs the power was good in all muscle groups, but there was some sensory ataxia, as shown by the heel-to-knee test, especially on the left. The triceps jerk was active on both sides, but the biceps and supinator jerks were absent. The abdominal reflexes were very active. The knee jerks were present on both sides, but the ankle jerks were absent. Plantar response was indeterminate. There was no loss of appreciation of pin-prick or light touch, and some hyperaesthesia was present in the lower limbs. The sense of position was normal and Romberg's sign was positive. Sensibility to deep pain was much diminished, but the vibration sense was normal. There was no astereognosis. At first some difficulty was experienced in micturition, but this soon disappeared.

Investigations.—The cerebrospinal fluid was normal in appearance, with no increased tension; cell count, 2 per c.mm.; albumin, 70 mg. per 100 ml.; globulin, 10 mg. per 100 ml.; colloidal benzoin reaction, 0000022200000000; Kahn test and Wassermann reactions, negative

Radiograph showing bony changes

The Kahn blood reaction was also negative. Radiographs showed marked bony changes (see fig.). I am indebted to Dr. Nessem Abu Saif, professor of radiology at Kasr-el-Aini Hospital, for the following report: "There is deformity, partial collapse, and backward subluxation of C3, 4, and 5, with bony condensation of an ivory appearance and irregular new bone formation, especially on the anterior aspects of these vertebrae. The intervertebral disks are preserved. This bizarre deformity is typical of Charcot's joint disease."

Treatment.—The patient was put on antisyphilitic treatment and received 500,000 units of penicillin daily for 10 days; 10 injections of N.A.B., given twice weekly, the dose rising from 0.15 g. to 0.6 g., then 0.6 g. weekly for 10 weeks; and "bismotab" 1 ml. weekly for the last five weeks. During the whole period he was taking by mouth liq. hyd. perchlor. $\frac{1}{2}$ dr. (1.75 ml.) and pot. iod. 10 gr. (0.65 g.) three times a day.

Under this treatment there has been definite clinical improvement. Micturition is normal. He can walk better and there has been a return of power to a limited extent of flexion at the elbow. He can now bring his hand to his mouth. The shoulder muscles, however, are still very weak, and the small muscles of the hand on both sides are very wasted. The sensation of pain in the right shoulder, of which he complained, is much less, but is felt occasionally. It is considered unlikely that any more improvement can be expected.

The interest of the case lies in the fact, first, that while the clinical picture is atypical, and there are only very mild changes in the C.S.F. to indicate an old syphilitic infection, the changes in the cervical spine are typical of Charcot's disease of the spine; secondly, that the cervical spine is very rarely affected by tabetic arthropathy, the lumbar region being the commonest site.

PHILIP E. J. CUTTING, M.D., M.R.C.P.,
P.M.O., Church Missionary Society Hospital, Old Cairo

The Ministry of Health has issued a new list of treatment centres for venereal diseases. It covers the United Kingdom and Eire, and gives the names of the centres, the towns where they are situated, and the times when patients are seen.

Reviews

GROUP PSYCHOTHERAPY

The Practice of Group Therapy. Edited by S. R. Slavson. Foreword by Nolan D. C. Lewis, M.D. (Pp. 271. 21s.) London: Pushkin Press.

The treatment of patients in groups can now be regarded as an essential part of the psychotherapist's equipment. As in the case of individual therapy, the procedures vary as widely as psychotherapists' attitudes to the behaviour disorders. The editor of this volume—one of the best-known American workers in this field—and his contributors follow psycho-analytic thought, for the methods described most fully are those founded on the appreciation of transference relationships and in particular on the adequate treatment of the hostile feelings that enter into these relationships.

Slavson and his co-workers have developed two main methods—activity group therapy and interview group therapy. In the first, which is for children, the therapist provides a socially tolerant environment in which dominant themes of the inner world can be acted out. The therapist does little or no interpretation, and the modifications in the child's inner world which enable him to improve his relations with his outer world take place by the acting-out process in the "permissive" environment. The second method, the one of choice for adults, consists in spontaneous discussions by the group. Here the therapist makes interpretations through which the members gain insight into, and hence release from, their difficulties. The actual processes within groups conducted along these two main lines are clearly described in a series of contributions on a variety of psychological disturbances. Those starting to give group treatment will regret the omission of a detailed account of how adult groups are begun—how to introduce the idea of group treatment and to conduct the opening sessions.

The writers confirm the view that group therapy in skilled hands has very great potentialities. Equally, they expose the fact that much critical thought and systematic study are needed on both principles and practice. It is not at all clear, for example, why the composition of groups has to be so carefully planned. Again, in the interview-therapy method it is difficult to see why "relationship group therapy" is described as a distinct variant. The latter method is characterized by the analysis of the transference relationships between members of the group and between them and the therapist. But if the basic principles of psycho-analysis are accepted—and it is stated that these are fundamental to all brands of psychotherapy—we may ask whether the members of a group can achieve full insight into their difficulties without these interpretations. How else can the innumerable projections and other unconscious manipulations of the relationships in the group be brought to the patients' awareness? Moreover, in the acting-out process of activity therapy it is difficult for a psycho-analyst to imagine an unconscious need-system undergoing a radical change unless the patient gains insight through interpretation. The cases quoted certainly seem to have benefited, but it is not clear whether the improvement is the result of acting-out or of the interpretations that must have been given by other members of the group. Spontaneous testing of fantasy against reality is one of the most important ways in which the child's personality develops, so that there is no question of denying the possible effects of such a process. It is therefore puzzling to read that pre-school children, in whom the acting-out process would normally be most prominent, are not suited to activity therapy since they apparently have to be given insight through interpretation. It is possible that the methods of describing the cases and the interpretative procedures are

These and many other points are no doubt in the minds of the writers, who are to be congratulated on their pioneering work in this very complicated subject. This is a most useful volume for all psychotherapists, and a fitting word of praise is due to the editor on the way he has obtained a unified work by applying his subject to his contributors.

J. D. SUTHERLAND.

PROTEIN IN NUTRITION

Proteins and Amino Acids in Nutrition. By Melville Sahyun, M.A., Ph.D. (Pp. 566; illustrated. £2 5s.) New York: Reinhold Publishing Corporation. London: Chapman and Hall. 1948.

This book is about the all-important role of protein in nutrition including the consequences of deficiencies of protein and, within the limits of knowledge, of specific amino-acids. Consideration is also given to the metabolic interrelations between protein and carbohydrates, fats, vitamins, and mineral salts. Dr. Sahyun has acted as editor and has written the foreword and the chapter on "Plasma Proteins and their Relation to Nutrition"; the introduction is by H. B. Lewis, and the fourteen other chapters are written by experts in their own particular fields. For example, H. H. Mitchell writes on "The Biological Utilization of Proteins and Protein Requirements," and H. J. Deuel on "Caloric, Vitamin, and Mineral Requirements with particular reference to Protein Nutrition." Although there appears little on protein digestion in the ruminant, the nutritive aspects of meat and meat products are considered, and H. J. Almqvist gives an account of the amino-acid requirements of avian species. The special problems associated with pregnancy, paediatrics, wounds, and immunity are considered, as is also the protein nature of toxins, antitoxins, filtrable viruses, and related substances. One of the most interesting chapters is that on the history of the significance of proteins in nutrition.

A compilation by many authors generally lacks unity, but the authors of this book have combined to present a very interesting and useful series of essays which are well knit together. The references are adequate for the purpose, and at the end of the book there are two appendices: (1) "Proximate Composition of American Food Materials"; and (2) "Nutritive Value of 100 g. of Selected Foods, Edible Portion." These have been compiled from U.S. Department of Agriculture publications.

D. P. CUTHBERTSON.

LETTERS OF NOAH WEBSTER

Webster, Noah. Letters on Yellow Fever addressed to Dr. William Currie. With an introductory Essay by Benjamin Spector. Supplement to the *Bulletin of the History of Medicine*. No. 9. (Pp. 110. \$2.) Baltimore: The Johns Hopkins Press 1947.

The subject matter of these letters is of considerable historical interest, though intrinsically of little importance, because, though they embody the views of "an intelligent layman" on the origin and propagation of yellow fever, they are views held before the work of Finlay and of Reed, Carroll, Lazear, and other members of the American Commission who cleared up so much which had till then been obscure. Webster does not, as he states, wish to "intrude into the province of the [medical] faculty," "not being acquainted with medical science myself," and later, "Facts are not to be reasoned away by airy speculation." Yet in 25 letters written between Oct. 26 and Dec. 21, 1797, he bases on personal observation and opinions and facts communicated to him by "medicinal friends" a mass of air speculation.

Webster ridicules the idea of the importation of yellow fever generally. He mixes up all sorts of infections, thus "Plague is a higher grade of the yellow fever, as the yellow fever is of the typhus or contagious fever"; again, "The symptoms [of the plague of Justinian, A.D. 542] were exactly the same as we observe in the violent case of yellow fever." "Dysentery is acknowledged . . . to be the same disease as yellow fever falling on the intestines."

These quotations will suffice to show that the letters form a curious collection. The main interest of this book and its most absorbing is the introductory chapter by Dr. Benjamin Spector, telling of the life of the author and giving a résumé of his ideas. Noah Webster was born at West Hartford, Connecticut, on Oct. 16, 1758, and died at the age of 85 in 1843. He graduated at Yale University, qualified as a barrister being admitted in 1781, and published the *American Spelling Book* in 1783 (60 million copies of this were issued). Ten years later he became editor of two papers, a daily and a bi-weekly. He took much interest in copyright activities:

so passed on to politics. As side-lines he studied climatology, vital statistics, and health questions, and in 1799 published his *History of Epidemic and Pestilential Diseases*. He was in advance of his times in advocating taking the public into confidence on general health matters.

Dr. Rush, of Philadelphia, was much impressed by the *Letters* and tried to find a publisher, but, as he said, practically all printers and booksellers believe that yellow fever is imported and are therefore prejudiced against Webster's (and Rush's) opinions. Consequently Rush suggested getting them printed in London and promised the author an introduction to Dr. Lettson, but nothing came of this, and the letters were never published except in their original form in 1797 in the *New York Commercial Advertiser*.

Noah Webster, by reason of his zeal and persistence, deserves to be included among non-medical men who have furthered interest in health subjects—men such as Louis Pasteur, Edwin Chadwick, Jeremy Bentham, John Howard, Mary Wortley Montagu; and the student of medical history owes a debt of gratitude to the editor of the *Bulletin of the History of Medicine* for making these letters and the introductory essay available to a wider circle of readers.

H. HAROLD SCOTT

COMPULSORY HEALTH INSURANCE

The Issue of Compulsory Health Insurance. Edited by the request of Senator H. H. C. of the Subcommittee on Health of the Public Welfare. By George H. H. C. (Pp. 271. No price.) Washington 1948

The latest addition to the steady stream of books on this subject coming from the U.S.A. is issued under the auspices of the Brookings Institution, which is "devoted to public service through research and training in the social sciences." It was prepared at the request of the Senate Committee on Labour and Public Welfare. The Institution was told that the issue to be examined was "not whether it shall be the policy to make medical care available to those who cannot afford to pay the full cost, but how the activities in this field should be planned, integrated, and systematized." It was further said that two major plans are under Government consideration: (a) to make grants in aid to the several States and let them design a programme to suit their own convenience, grants being given only to those States whose programmes comply with central requirements, and (b) to adopt a complete Federal compulsory health insurance. The Institution was asked to submit a report which would examine "all the evidence in support of or against both these plans."

The Institution committed the task to two men both of whom had large experience in medical and general sociology, and their report is a testimony to their thoroughness. There are masses of statistics; every imaginable question on the subject is asked and answered with apparent impartiality. In their summing up the investigators make some novel suggestions arising out of their experience. They say "the average lack of medical care in persons belonging to the 2,000 dollar and over income group at 1941 levels is due more to failure to give medical care high priority than to lack of income." There is a steady movement from the lower income levels. In 1930-6 about one-seventh of the population had incomes of from 2,000 to 5,000 dollars. In 1946 half the population was in this higher range. The figures of expenditure show that more money is spent by this group on cars, liquor, tobacco, and recreation than on medical care, which is supposed to be a necessity. The investigators suggest that much of the problem could be met if the public could be induced to give medical care its due priority, being encouraged to join voluntary approved agencies by suitable income-tax allowances. They agree that there would be a substantial number unable to meet the cost of medical care on any insurance system, whether voluntary or compulsory.

The book well deserves the attention of all interested in the subject. Its origin would seem to show that the politicians mean to do something about it—but then they have been saying so for some years now, and so one never knows. Perhaps they are waiting for a Gallup Poll.

FINANCE OF THE N.H.S.

The supplementary estimate of £58 million for the National Health Service may be in part an indication of medical needs formerly unsatisfied, but it is also a sign that the Government was far out in its estimate of the cost of the Service introduced in July last year. For example, the supplementary ophthalmic services, estimated to cost £2½ million, are now expected to require over £14 million, and the estimate of £8 million for general dental services has swollen to the figure of £20½ million. These matters are being debated in the House of Commons as we go to press. Large though these increases may be (and the additional £52 million needed for the Ministry of Food) they nevertheless bring home to the country the importance of these two factors in the health of the nation—food and medical services. In this week's *Journal* Dr. Ffrangcon Roberts, in his role of vigilant critic of the contemporary medical scene, shows how the estimates have risen since the Beveridge Report in 1942. While it may be expected that the demand for spectacles and dentures will diminish after present defects have been made good, there remains the costly programme for building health centres and expanding the hospital system. Sir Frederick Menzies has already sounded a warning note¹ on hospital costs. He points out that in September, 1939, the cost of maintenance of a bed in one of the best of the voluntary hospitals in London was about £5 per week; the corresponding cost to-day is about £15 per week. Sir Frederick believes that unless steps are taken to reduce hospital costs these may have serious repercussions on other medical services. The *Observer*² says: "In principle it is hard to quarrel with the present social policy of the Government, bitter though its price is"; and it asks whether the people who have demanded the services now available are willing and able to foot the bill. The Government may yet consider it wise to ask the patient to make token payments for a doctor's services and for prescriptions. If this were considered feasible it would deter people from making unwarranted calls upon the doctor's time, and unnecessary demands for pills and potions.

However necessary institutions and administration may be, it is essential that they should not be financed at the expense of the medical men and women who do the work of caring for the sick. That many doctors are suffering financial hardship has been admitted by Labour Party spokesmen in the House of Commons, and public opinion is aware of the discrepancy between the doctor's reward and that of those working in the ophthalmic and dental services. Everyone knows, as Mr. Fred Messer, M.P., put

it, that the present situation cannot remain as it is. The first thing to be done is to remedy existing injustices; and the second—linked with the first—is to provide conditions that will continue to make medicine, and general practice in particular, a career that will attract able men into its ranks. It is, of course, not fair to pass judgment on a service barely eight months old, but the present prospect of overwork and financial anxiety is not one likely to appeal to the parents of a youth wanting to become a doctor. What can be alleviated now is the financial anxiety. Overwork can be remedied by the gradual distribution of medical men from over-doctored to under-doctored areas and by an increased entry into the profession.

In this week's *Supplement* appears a report on the remuneration of general practitioners drawn up by the General Medical Services Committee. This will be the main subject for discussion first at the Conference of Local Medical Committees on March 3 and later at a Special Representative Meeting on March 29. There are many ways in which the medical profession could have sought a solution to the problem of underpayment for work done. The General Medical Services Committee has adopted the approach of the Government when it decided to establish a Central Fund from which enough money could be distributed to general practitioners in terms of the recommendations of the Spens Report. The size of this Fund was related to an expected number of 17,900 principals. But on the appointed day rather more than 20,050 practitioners had joined the Service, and the number now is approximately 20,500. Allowing for assistants on the list there are at least 20,000 principals now in the Service. Therefore the Central Fund should be adjusted by about £3½ million to provide for the additional 2,000 or so principals in the Service. The remuneration advocated in the Spens Report was in terms of the 1939 value of money and the Report advocated that an adjustment should be made by applying what has become known as the betterment factor. In 1946 the Government decided on a factor of 20%—a figure which was not, and has not been, accepted by the medical profession. At that time it was estimated that the cost of living for the middle classes had increased between 45% and 50% over 1939. In 1948 this figure had risen to 85%. It will be recalled that the Government's 20% betterment factor was added to net remuneration while it applied 55% to practice expenses. These two taken together amount to a betterment figure of 34% to gross remuneration. The view of the General Medical Services Committee is that on the basis of an increase in the cost of living from 45% in 1946 to 85% in 1948 the betterment figure applied to gross remuneration should be in the region of 70%. This alone would increase the Central Fund by more than £16½ million.

These proposals for increasing the Central Fund will be debated at the two important meetings next month, and whatever modifications may be made in resolutions passed by the Association, backed up by the solid evidence of indisputable facts, will press the profession's case with the Ministry of Health. The Committee discussed the way in which the sought-for increase in the Central Fund should be distributed in order to relieve existing hardship, to fulfil the recommendations of the Spens Report, and to provide

¹ *British Medical Journal Supplement*, 1948, 2, 220.
² Feb. 13, 1949.

a solution that the profession and the public would regard as fair. It is obvious that the doctors who have suffered most (apart from rural practitioners, now helped by the increased Mileage Fund) are those with small lists in health resorts, seaside towns, and residential areas whose private practices have by the decision of the patients become public practices. The Committee therefore is recommending that the increased money to be asked for should be used to increase the capitation fee for the first 1,000 patients on the lists of all practitioners. If, for example, the Association succeeds in securing £16½ million more for the Central Fund this would mean that the capitation fee for the first 1,000 patients would be 35s. With the increase of the capitation fee for the first 1,000 patients on a doctor's list existing hardship would be relieved and at the same time the building up of large lists would not be encouraged.

The demand of the profession for adequate remuneration comes at a time when the Government and the country are, by the supplementary estimate of £58 million, being made uncomfortably aware of the cost of the National Health Service. If the Ministry of Health receives the proposals as sympathetically as it did the proposal for the increase of the Mileage Fund the Treasury will no doubt resist the increase of expenditure demanded. But if saving has to be made it must not be made at the cost of the men and women who do the work of medicine. Parliament and the people demanded the Service and ignored those who suggested that such a service should be introduced gradually, so that by trial and error lessons could be learnt and mistakes avoided. In May of last year the medical profession with much reluctance decided to enter the Service, but during the past eight months has loyally co-operated with the Ministry to make it work as efficiently as possible in the circumstances. In the result doctors generally have been grossly overworked and some of them have been on the brink of financial disaster. If the Service is to evolve into what all would wish to see it be, then the proper payment of those who work in it must be the first consideration of the Government, because good work cannot be done in an atmosphere of discontent and a sense of injustice, and medicine will come to be looked upon as a profession to avoid.

TSETSES OVER AFRICA

It was only after the first world war that the French, British, and Belgian authorities began to realize how widespread and how serious was trypanosomiasis in man and animals. The economic difficulties which affected Africa no less than other countries in the early 'thirties put a stop to many promising schemes for the control of sleeping sickness. At that time the British Treasury made no grant to finance such schemes, and each colony was dependent on its own financial resources or on such money as it could raise by loan. Despite this crippling poverty much was done, but with the passing of the Colonial Development and Welfare Act in 1940 and its augmentation in 1945 more ambitious schemes for the control of trypanosomiasis could be planned. The first international conference on trypanosomiasis was held in Lagos while the war was still on, and the latest was held

in London last week. Representatives attended from the United Kingdom and Colonies, France, Belgium, Portugal, South Africa, Southern Rhodesia, and the Sudan. The proceedings were held in private, but we understand that about twenty papers were presented, including reports on field trials with "antricide" in the Sudan and East Africa.

Four excellent reports on what has been already done have recently been prepared for the Tsetse Fly and Trypanosomiasis Committee appointed by the Secretary of State for the Colonies. Professor P. A. Buxton's contribution is an account of trypanosomiasis in East Africa¹ and Professor T. H. Davey's of conditions in West and Central Africa²: both reports contain the results of fact-finding tours. Included in the other two reports,^{3,4} both written by Dr. T. A. M. Nash, are interesting accounts of original work: that dealing with the tsetse flies of West Africa will long remain the standard work on this subject. The other is a description of the Anchau experiment in Nigeria and shows how an area can be rendered tsetse free, and the whole life of the African raised to a higher plane, provided his willing co-operation is obtained by careful consideration and by explanation of every step. Saunders,⁵ writing from the Gold Coast, has also insisted on the importance of what he terms "infiltrative propaganda" before undertaking trypanosomiasis campaigns. There are many difficulties, however, in propaganda, for the interpreter is considered not as a medium for conveying ideas but as a middleman with a prescriptive right to commission and emolument from both sides.

It is obvious that the control of trypanosomiasis presents different problems in different parts of Africa. The variables include the species and strains of trypanosome, the species of tsetse common in the area, the presence of big game, the prevalence of other epidemic diseases, and the psychological make-up of the African. The difference in the response of *T. gambiense* and *T. rhodesiense* to drugs is already well known. In Nigeria infections due to *T. gambiense* are more easily controlled by chemotherapy than those in the Gold Coast. Measures to control tsetses obviously depend on the species present: where *Glossina morsitans* is predominant, destruction of all the big game will often end trypanosomiasis. Such measures have enabled the reclamation of many thousands of acres in Southern Rhodesia, but as a rule *G. morsitans* is only one of the tsetses present. The inhabitants of some areas, especially in the Northern Territories of the Gold Coast, have been decimated by recurrent epidemics of influenza and cerebrospinal meningitis. When the adult male population is reduced below a certain level communal hunts cannot be organized, game increases, and so does *G. morsitans*. As a result farms are destroyed, and only those close to the village can be kept in cultivation. It follows that the fallow period is shortened, the fertility of the soil decreases, and malnutrition and sleeping sickness reinforce each other.

Little is known of the reasons why some tribes readily submit to the activities of sleeping-sickness diagnosis and

treatment campaigns while others do not. How closely trypanosomiasis is bound up with the culture patterns of each tribe is shown by a consideration of the village pond, anathema to the sanitarian because it provides all-the-year breeding conditions for mosquitoes and tsetse flies. For the villager, however, the pond provides green plants which, when reduced to ash, are essential as a source of salt. In some areas the ponds contain fish: these are sacred, for either the lives of particular fish may be connected with the lives of particular villagers or the fish may house the souls of the ancestors. In other areas the banks of the pond form the local latrine, and the fish eat up the faecal matter. Any interference with the village pond may thus have serious repercussions.

In many parts of Africa trypanosomiasis of cattle and pigs is as serious as trypanosomiasis of man, for methods of effective control have hitherto been lacking. The use of aeroplanes for spraying D.D.T. has opened up a new approach, and the discovery of the phenanthridinium compounds marked a first step in chemotherapeutic control. A further advance will be made if the new drug antrycide (4-amino-6-(2'-amino-6'-methylpyrimidyl-4'-amino) quinaldine -1:1'-dimetho salts) lives up to expectations. We gave some information about antrycide in a recent annotation,⁶ and a short account by the late Dr. F. H. S. Curd and Dr. D. G. Davey of the experimental evidence on which claims for the drug are based has now been published.⁷ *T. congolense*, *T. vivax*, *T. brucei* of cattle, and *T. evansi* of camels appear to be controlled, but the action on *T. simiae*, a pig trypanosome, is unrecorded. The cost of each injection will work out at approximately 2s 1½d., and since it will be necessary for prophylaxis to reinoculate cows at intervals of six or possibly four months the cost to the Government or to the individual cattle-owner will be considerable—a matter of some moment in a country such as Nigeria, where the average annual income of the population works out at twenty shillings. The question of drug fastness has still to be intensively studied, and, as in the case of proguanil, it will be some time before the true value of antrycide can be assessed.

Although eradication of the trypanosomes which infect cattle and pigs is a most important step in the supply of additional meat, there are other basic difficulties which will have to be overcome. In many areas there are already far too many cattle for the pasture available—this is because cattle represent currency and therefore power and prestige. Just as a dirty, torn Treasury note is still worth its face value, so a miserable scrawny cow is still a cow and represents a certain part of a bride-price or a sacrifice. Many cattle-owning African tribes, the Fulani in particular, are not attracted by anything that Western civilization can offer, and any attempt to reduce the number of cattle in order to improve the breed and prevent soil erosion is met by passive if not by active resistance. At present the quality of the stock is far too poor to fit it for the export trade. Thus, before cattle can be looked upon as an article of commerce by the African, there will have to be a radical change in animal husbandry, and this in many tribes will involve a complete change in social attitudes and culture patterns. When once this has been done it will be essential to replace thousands of square miles

of elephant grass by more nutritious pasture, to provide water, and to stop soil erosion.

At present meat may not be imported into the United Kingdom from countries where virus diseases such as rinderpest or swine fever exist because of the risk of infecting domestic herds. Swine fever is rife in East Africa, and rinderpest still exists all over tropical Africa, game animals forming a reservoir. The problem of rinderpest is already being tackled in British colonies with the goat-adapted virus introduced by Edwards, but if the disease is ever to be controlled international action is essential. Only when these difficulties have been met will it be possible to organize marketing and to arrange for the canning of low-grade beef and pork and their residual products. In addition, as Rita Hinden⁸ has pointed out, it will also be necessary to have cold storage at the abattoirs, refrigerated transport to the ports, and cold storage and suitable loading facilities at the ports. Anyone acquainted with the existing conditions on African railways or at African ports will realize what this involves. The great difficulty, however, perhaps more important even than the tsetse fly, is the attitude of the African cattle-owner. This will not be easy to change, and even if it can be done the question may well be asked, and in fact has already been asked by Africans, "How far are Western European nations, comparatively well fed by African standards, justified in removing from Africa first-class proteins in the shape of meat and eggs when African populations are still living on diets that are grossly deficient in proteins?"

CHEMOTHERAPY IN LUPUS VULGARIS

Secondary pyogenic infection of a tuberculous process may respond well to sulphonamide therapy, with improvement in the general condition of the patient and in the tuberculous process itself. In 1940 Domagk¹ described an inhibitory action of sulphathiazole on the growth of the tubercle bacillus *in vitro* and in experimental animals, and encouraging results were reported by Malluche² in patients with non-pulmonary tuberculosis and by Baumann³ in patients with pulmonary tuberculosis. Other investigators have claimed some successes with certain sulphones such as promin and diazone. In 1946 Domagk and his colleagues⁴ showed that it was the thiazol and thiodiazol groups which were responsible for the inhibitory effect, and they reported on two compounds of the thiosemicarbazone group (named P698⁵ and Q242) whose action, unlike that of sulphathiazole, was unimpaired by *p*-aminobenzoic acid and other antsulphonamide factors. Moncorps and Kalkoff⁵ have reported on the use of these substances in the treatment of 26 patients with severe ulcerating lupus of the face who had previously been treated with ultra-violet light, caustics, grenz rays, and by other means without permanent improvement. All were admitted to hospital so that renal function tests and blood investigations could be carried out and toxic reactions controlled. The drugs, mixed with equal parts of sulphathiazole, were given over a period of several months, and the dosage was regulated according to the tolerance of the patient; in some cases 0.125 g. of the mixture was given eight times a day, in others 0.25 g. four times a day. Blood changes such as a mild secondary

anaemia or slight leucopenia were infrequent and occurred usually in the patients whose lupus improved considerably; the blood returned slowly to normal after cessation of treatment. Rarely the urine contained albumin and hyaline casts. In some cases pyrexial therapy appeared to produce a further improvement, particularly after drug treatment had been temporarily suspended owing to toxic reactions. Of the 26 cases treated, four were completely cured, three considerably improved, 10 made definite progress, six made only slight progress, and three remained unchanged. In three of the cases areas of skin treated with the Finsen lamp during the period of drug treatment improved more rapidly than untreated areas. The authors stress the importance of continuing treatment after apparent clinical cure and mention the danger of producing a resistant strain of tubercle bacilli if treatment is cut short without good reason. This report does not make extravagant claims for the cure of lupus vulgaris, and the importance of environmental factors in the assessment of therapy is stressed. The work is of interest in relation to the investigation of the treatment of leprosy by chemotherapy.

SYRINGE STERILIZATION

During the latter part of the war the Medical Research Council appointed a committee to consider methods of sterilizing syringes, and the result of its labours was the now generally familiar memorandum, *The Sterilization, Use, and Care of Syringes*.¹ The chief conclusion reached was that no chemical method can be depended on to sterilize a syringe and that absolute safety can be assured only by dry heat at 160°C. or by autoclaving. The use of certain chemicals was also objected to on account of their possible effects either on medicaments injected or on blood withdrawn for diagnostic tests. Provided that they were applied only to syringes used for aseptic purposes, methods such as simple boiling or immersion in spirit which do not achieve absolute sterility were considered permissible in certain circumstances.

At about the same time an inquiry into the same subject was undertaken in Switzerland by a commission appointed by the Swiss Society of Surgery. Its findings appeared in the form of a monograph by one of the members of the commission, Dr. Ernst Baumann.² A second edition of this has now appeared and is of particular interest, since it discusses the M.R.C. memorandum at considerable length and disagrees with it in several directions. Dry heat is granted to be an ideal method when feasible, but a higher temperature is recommended: this is stated as 180°–200°C., and the time-honoured Continental indicator of its attainment, the browning of cotton-wool, is also mentioned (but not the fact that this roasting of cotton-wool volatilizes tarry material which may condense on the syringe and needle). Autoclaving is approved, as also is a similar method almost unknown in this country, that of boiling under pressure; this would of course be feasible in any pressure-cooker. The remaining alternative method of absolute sterilization is boiling at atmospheric pressure in a disinfectant solution: this is a proceeding suggested for the general practitioner with neither time nor equipment for anything else. Four solutions are suggested—2% sodium carbonate with or without 0.1% of formalin, 2% "desogen" (a quaternary ammonium compound evidently widely used in Switzerland), or 1 in 20,000 "merfen" (phenylmercuric borate). These reagents have to be washed out of the syringe with sterile distilled water

before use; and this may seem to some English minds to be a serious objection to such methods, because supposedly sterile distilled water is a notorious source of contamination. If, as suggested, a fresh ampoule is used on each occasion, this danger should be obviated. The Swiss commission has been at great pains to show that such traces of these disinfectants as may remain in the syringe can do no harm, and elaborate pharmacological tests are described showing that adrenaline, insulin, strophanthin, penicillin, and certain vitamins and hormones are unaffected by them.

Four other solutions are specified, two containing formalin, one desogen, and one merfen, in which syringes used only for aseptic purposes and otherwise free from any danger of contamination may be placed between one use and another. This is almost the only concession made in an otherwise strict insistence on methods which can be depended on to ensure absolute sterility. It is interesting that there should be some conflict of opinion between experts in different countries on so apparently simple a matter as this. It would also be interesting to know what proportion of doctors in each country disregard all such recommendations and continue to use methods which all authorities are agreed in condemning.

FISH POISONING

Among the medical surprises of the recent war were the widespread incidence of mite-borne typhus in South-east Asia and the presence of Q fever in Southern Europe. In both the infections were the result of non-immune individuals going into regions not usually visited in normal times and contracting diseases which must have been present among the indigenous populations. An experience of the opposite kind has recently been reported by Ross,¹ who observed as an aftermath of war an illness previously unknown in a native population. At Fanning Island, in the Central Pacific, a fish-eating population, who had a sound practical knowledge of which fish were good to eat and which species or organs were not, in 1945 began suffering from an illness characterized by a fairly sudden onset of gastro-intestinal symptoms preceding or following paraesthesia of the limbs, face, and body. The illness followed a fish meal 3–24 hours previously. The body temperature was subnormal, pupils were usually contracted, and general weakness was a common complaint.

In the following 18 months nearly half the population had been attacked by this illness. After feeding fresh fish to cats, dogs, and domestic ducks Ross was left in no doubt about the immediate cause. In the animals paralysis was the prominent sign. All the human patients recovered, but sometimes it was several weeks before the sufferer was quite well. Europeans appeared more susceptible than the natives. Discarding of the internal organs of the fish followed by thorough washing before cooking did not prevent the onset of symptoms, and it was quite clear from experiments with cats that the skeletal muscle of the fish contained the poisonous substance.

Ross found that both migratory and non-migratory species of fish were involved. He next observed that all fish causing poisoning had been caught in localities where surplus war material, comprising metals and condemned food, had been dumped in July, 1945. Fish poisoning first appeared four months later. The signs and symptoms observed in the cases on Fanning Island resembled those of mussel poisoning in North America,² in which death from respiratory paralysis may occur, but in the latter the

² Sommer, H., Wheldon, W. F., Kofoid, C. A., and Stohler, R., *Arch. Path.*, 1937, 24, 537.

³ Gibbard, J., and Nanbert, J., *Am. J. nat. Hist.*, 1948, 22, 559.

¹ M.R.C. War Memorandum No. 15, 1945, H.M.S.O., London.
² *Sterilisation und Sterile Aufbewahrung von Spritzen und Hohlnadeln*, 1948, Basel.

onset was more rapid. Since it has been shown that the mussel poisoning is due to the dinoflagellates of the genus *Gonyaulax*, a plankton organism on which the mussels feed, Ross suggests that the fish poisoning at Fanning Island may have had a similar origin, and that the plankton and other creatures on which the fish feed might well be poisoned by substances originating in the deteriorating dumped war material. It is to be hoped that the physiological properties of the toxic substance or substances are being investigated and, if possible, that their chemical nature will be ascertained. Ross treated his patients by washing out the stomach in serious cases, the administration of cathartics and a nux vomica mixture, the application of local heat to the abdomen, and rest in bed.

ARTERIAL EMBOLISM

The question of whether or not to operate in cases of embolism of the limb arteries is one on which there is divergence of view. Considering the high mortality recorded in published series of cases, in some exceeding 60%, and the poor subsequent outlook for patients with severe cardiac disease, some authorities now advocate conservative methods of treatment only; of these heparin, sympathetic interruption by paravertebral block, and intermittent venous occlusion are the most important. By thus abolishing the spasm of collateral vessels and preventing a spreading thrombosis in the main arterial trunk approximately two-thirds of the affected lower and nearly all the upper limbs can be saved. Others believe that the chances of avoiding gangrene are improved by operative removal of the embolus, at least from the lower limbs, and in a recent paper Warren and Linton report that survival of the lower limb was secured in 15 out of 18 cases (83%), the mortality being no greater than in the cases treated conservatively. It must be realized that these are the results of specialists in vascular surgery, with a wide experience of blood-vessel suture and of the care of ischaemic limbs, and it is unlikely that such success can be achieved by the general surgeon. Warren and Linton consider that embolectomy is the treatment of choice, but not if the embolism is in the popliteal artery nor in patients with advanced arteriosclerosis. As a general rule 10 hours is regarded as the longest period which should be allowed to elapse between impaction of the embolus and operation if the treatment is to have a good chance of success; but operation has proved successful up to 60 hours after impaction, and Warren and Linton do not believe that a definite time limit should be set. In nearly 90% of their cases the source of the embolus appeared to be within the heart, and it is noteworthy that little more than a half of the patients suffered the severe pain at the onset which is one of the classical symptoms.

A rational view would concede the value of both lines of treatment. Operative intervention is indicated in patients whose general condition and cardiac reserve are good enough to withstand the shock not so much of operation conducted under local anaesthesia as of the sudden return of blood flow in an ischaemic limb. Other prerequisites for operation are absence of severe atheroma and accessibility of the embolus without the risk of damaging collateral channels. In this connexion the results of Warren and Linton show that operative treatment is most successful when the site of the embolus is at the bifurcation of the femoral artery; fortunately this is much the commonest site for the lodging of emboli. Whether or not operation is decided on, in embolism of the limb arteries treatment

by heparin and paravertebral sympathetic block should be carried out at the earliest possible moment, and, when there is doubt, failure to secure improvement in the temperature and colour of the extremity within an hour of the latter procedure may well tip the scales in favour of operation.

NUFFIELD HOSPITALS TRUST

The Nuffield Provincial Hospitals Trust, endowed with a million Morris Motors shares, was founded in 1939. Its purpose was to co-ordinate on a regional pattern the hospital and ancillary medical services in the provinces and to make provision for the carrying on or extension of such services as were necessary to complete the co-ordination. The National Health Service Act has meant a redirection of its activities, not the cessation of them, and has afforded an opportunity for a report on what the Trust has accomplished in nine years. This report is published by the Trust from its offices at 12, Mecklenburgh Square, W.C.1.

Before the Trust came on the scene the co-ordination of hospital services had been much talked about, but little had been done. The Sankey Commission set up in 1935 recommended the division of the country into regions, with the formation of regional councils and a central council. It was this report, together with the example of the Joint Hospital Board in his own Oxfordshire and adjacent counties, which led Lord Nuffield to form the Trust. The scheme for regionalization which it put forward covered half the country. The Trust also embarked on a series of hospital surveys, and when, a little later, the Government announced its intention of making similar surveys it accepted the offer of the Trust to organize and finance them in the provinces. Of the ten survey teams set up seven were appointed by the Trust.

Among other projects supported by the Trust, always with a view to the better co-ordination of hospital services the most noteworthy was the setting aside of £100,000 for the creation of the first professorship and Institute of Social Medicine in Great Britain—at Oxford under Professor J. A. Ryle. A grant of £15,000 was also made to the University of Birmingham towards the cost of a similar professorship there. Two experimental bureaux of health and sickness records have been set up—one in Oxford and the other in Glasgow. The Trust has interested itself in health services as affecting children, students, industrial workers, and others, and grants have been made towards work in university centres in psychiatry, neurology, plastic surgery, and other branches of medicine. The Trust also assisted Professor Sir Howard Florey's research team at Oxford. Altogether it is a record of large beneficence wisely and discriminately applied.

The Government's acceptance of regional co-ordination still leaves a number of problems unsolved. The Trust expects to find plenty of work still to do—making scientific studies of services, conducting practical experiments to test promising ideas, and demonstrating how new methods may be an improvement on old. It is at present making a job-analysis of the work of nurses in the hope of throwing some light on the stubborn problem of nursing recruitment and training. Another investigation concerns the functional design of hospitals. It is always an occasion of regret when voluntary efforts, if efficient, are superseded by statutory organization, although such supersession is in itself the highest compliment which can be paid to such voluntary enterprises. But it is a pleasing circumstance when, as here, the voluntary body remains at the statutory elbow to inform, to supplement, to prompt, to correct, or, more important, to avert the need for correction.

ROYAL COLLEGE OF SURGEONS

HUNTERIAN DINNER

The Princess Royal and the Duke of Gloucester attended the Hunterian Festival dinner at the Royal College of Surgeons in Lincoln's Inn Fields on Feb. 14.

Lord Webb-Johnson, who presided, read a message sent to the King from the Council and Court of Examiners expressing appreciation of his Majesty's interest as Visitor of the College, and stating that it was hoped soon to submit to his Majesty plans for the restoration of the College. The King in reply said he looked forward to seeing the plans for restoring the buildings towards which friends of the College in this country and overseas had contributed.

The Princess Royal, acknowledging tributes to the Royal Family, said it was the first time women had been present at the Hunterian dinner.

The toast "The College" was proposed by Mr. J. A. Beasley, High Commissioner for Australia, who spoke of the great value of the Sims Commonwealth Travelling Professorship, and of the Nuffield Benefaction which would make it possible for students to reside in the College. This would be much appreciated by medical men in the Commonwealth.

Lord Webb-Johnson, observing that ladies were present at the dinner for the first time, recalled that it was 40 years since Queen Mary, as Princess of Wales, had been present at the Hunterian Oration given by Mr. (later Sir) Henry Morris, and 22 years since the Princess Royal had attended the Oration by Sir Berkeley Moynihan, as he then was. The College of Surgeons was an important centre for postgraduate education, and so it came students from all parts of the Commonwealth. This was not a one-way traffic, and Fellows of the College went to the Commonwealth. Lord Webb-Johnson referred to the reciprocity now existing between the English and the Australian Colleges in respect of the Primary Fellowship. The teaching facilities of the College had been much increased by the munificence of the late Sir William Collins, and now Lord Nuffield's gift had made it possible to provide residential quarters in the College which would be especially welcomed by students from the Commonwealth.

The toast "The Guests" was proposed by Mr. L. E. C. Norbury and responded to by Mr. Norman Robertson, High Commissioner for Canada, and by Professor Lillian Penson, Vice-Chancellor of London University. Mr. Zachary Cope enlivened a distinguished occasion by proposing the health of the Hunterian Orator in verse, and the Orator, Mr. H. S. Souttar, replied.

LADY TATA MEMORIAL TRUST

The trustees of the Lady Tata Memorial Fund invite applications for grants and scholarships for research in diseases of the blood, with special reference to leukaemia, in the academic year beginning on Oct. 1. Grants of variable amount are made for research expenses or to provide scientific assistants for senior workers. Scholarships are awarded as personal remuneration; their normal value has been £400 per annum for whole-time research, with proportionate adjustment for work on a part-time basis where this has been approved. Applications must be submitted before March 31, and the awards will be announced by the trustees in June. Further particulars and forms of application may be obtained from the secretary of the Scientific Advisory Committee, c/o Medical Research Council, 38, Old Queen Street, Westminster, London, S.W.1. The grants and scholarships are open to workers of any nationality and in any country in which it will be possible to make payments in the coming academic year. The available information on this point regarding particular countries outside the sterling area will be supplied to intending applicants on request.

The British Council has arranged for Miss Emily MacManus, matron of Guy's Hospital from 1927 to 1946, to visit Turkey at the beginning of February for a two weeks' lecture tour. Turkey, too, is the problem of attracting girls to the nursing profession, and Miss MacManus has been asked to talk to lay and professional audiences about the life of a nurse in Britain.

Reports of Societies

ARTIFICIAL PNEUMOTHORAX

In the Section of Medicine of the Royal Society of Medicine on Jan. 25 there was a discussion on the place of artificial pneumothorax in the treatment of pulmonary tuberculosis. Sir ADOLPHE ABRAHAMSON presided.

Dr. F. H. YOUNG said that this subject was last discussed in the Section in 1921, the year in which he performed his first artificial pneumothorax. After twenty-seven years' experience he was still in doubt about the cases in which the treatment should be used, the details of the treatment, and the length of time for which it should be maintained. Since 1921 pneumothorax had had a tremendous vogue; in the early 'thirties it was given a trial whenever there appeared to be any justification for it. Opinion had now swung the other way, and a number of authorities regarded it as a dangerous practice only to be used in carefully selected cases.

Cases unsuitable for this treatment, even when it was possible, were those of dense fibrotic disease at the apex and those of tuberculous tracheobronchitis. Among the main complications were the recurrence of tuberculous empyema and bronchogenic spread, mainly to the other lung. After one or two refills a case should be screened if possible and reviewed as carefully as it was before induction was considered. At this stage, if there were extensive adhesions to a cavity area, the artificial pneumothorax should be regarded as having failed; where the adhesions were less unpromising it might be continued, but unless the cavities had disappeared by the end of a month other measures should be taken. Cavities which failed to collapse were the cause of a large proportion of disasters. He could recall only one case in which, without causing trouble, the pneumothorax had been maintained in the presence of an open cavity over a period of years.

Dr. Young proceeded to give figures from three sources—his clinic at Brompton Hospital, where he exercised only a general supervision, his clinic at St. Bartholomew's, and his private cases. He thought that the figures demonstrated the great advantage of having all the work in connexion with a given case—the selection, the organization of treatment, and so forth—in the hands of one individual from beginning to end. His figures did not bear out the view that the danger of great loss of function after pneumothorax was so considerable and so unpredictable—though unpredictable it certainly was—that it was better to do an upper stage thoracoplasty. It had been suggested that in a number of pneumothorax cases the cavities reopened. It was difficult to be dogmatic on that subject. He knew of one case in which a pneumothorax was performed twelve years ago and the lung allowed to expand, and now the cavities had reopened. But among his private cases he had had only two in which closed cavities had reopened.

At the Brompton Hospital he had been able to trace satisfactorily only about 40% of the cases. He had taken those cases which had attended the regional clinic for at least two years and had been followed either until death or grave illness or until the pneumothorax had been allowed to re-expand. At St. Bartholomew's 70% had been traced, and among the private cases 75%. In the Brompton series of 204 patients about 32% were dead or dying and 68% were alive and reasonably well. In the other two series combined there were 99 patients, and 11% were dead or dying and 89% were alive and mostly well. The proportion of unclosed cavities in the Brompton series was so much higher than in the others that it was thought better to exclude these cases, and, this being done, in the Brompton series 80% were alive and well, and in the other two series 95%. These figures referred only to those patients who came back to the clinic ambulant, and therefore the pneumothorax had been to some extent successful. His conclusion was that the revulsion against pneumothorax had been overdone; the revulsion should have been against pneumothorax work which was not done properly.

After the Sanatorium

Dr. F. R. G. HEAF said that it was not always appreciated what a change there was between the quiet, orderly regime of

the sanatorium and the rough-and-tumble of the average household to which the patient returned. This change of environment had the most profound effect on his clinical progress. Although a patient might appear to have stabilized himself under sanatorium conditions there was no proof that there were not foci which would become active when he returned home and ran the risk of minor infections and ailments, as well as having a change of diet. The physician in charge of the case should be in possession of all the relevant facts. The spacing of the refills might need to be a little more frequent after discharge from the sanatorium, owing to the increased amount of exercise which the patient undertook. The importance of a regular timetable for attendance at the clinic, both for the convenience of the patient and also for clinical reasons, should be stressed. In some centres refills were given without previous x-ray examination. Surely pneumothorax treatment for out-patients should be given with the same care and under the same control as to in-patients.

Owing to shortage of beds there was a tendency to send people out of the institution with uncollapsed cavities, tuberculous lesions of the bronchi, and so on. If pneumothorax treatment was held to be of use it should be carried to its completion before sending the patients out. Once having got the patient, it was better to do the job properly. Patients with bilateral infections often did well under sanatorium conditions but relapsed under domiciliary treatment; the patient was not able to stand up to the strain of the domestic environment. The termination of pneumothorax treatment could also bring about difficulties. Minor complications would occur, and it was important in domiciliary treatment to have arrangements whereby a patient could go back to hospital for one or two nights to have complications attended to under the best possible conditions.

Dr. Heaf concluded with a plea for the keeping of careful records and for the development of a system whereby after-histories might be followed for five or ten years. It was time for another big survey of the real value of artificial pneumothorax under present conditions and in view of the improvements in technique which had taken place since the former survey was made.

Limitations and Difficulties

Dr. PHILIP ELLMAN said that, no matter what form of treatment was contemplated, the general constitutional nature of the disease must not be forgotten, nor the possible influence of the inherited diathesis. Artificial pneumothorax as it was known to-day, used with discrimination and with adequate radiological control, had revolutionized the management of certain cases of pulmonary tuberculosis, but he proposed to speak rather of the limitations, disappointments, and difficulties of the method.

The procedure was attractive by reason of its simplicity, but the result depended very much on the anatomical nature of the collapse. Any incomplete pneumothorax should be abandoned in favour of other measures. The patient with acute febrile illness and active exudative disease was best treated initially by an adequate period of complete bed-rest. Streptomycin was a useful adjunct. The lapse of time gave an opportunity for the inflammatory process to subside and might even obviate the need for collapse therapy. In this connexion streptomycin might in future make pneumothorax a safe procedure. The risk of adhesions forming during the period of observation seemed to be more theoretical than real. In the presence of bronchial tuberculosis an ineffective pneumothorax might, by reason of symptomatic relief, give a false sense of security. "The physician's needle can be responsible for complications more dangerous than the surgeon's knife." It might have been to the advantage of the patient if the induction of pneumothorax had required as much skill as thoracoplasty. In many cases a thoracoplasty was to be preferred as an initial procedure to an ineffectual attempt to produce a pneumothorax.

On the mechanism of the closure of cavities there were opposing schools of thought. Bronchial obstruction was the chief factor in cavity closure. There was much to be said for bronchial drainage, and the use of the bronchoscope might avoid many complications. With regard to effusions, many of these were small, containing no tubercle bacilli on examination, but he regarded as potential empyemata effusions which began

to contain tubercle bacilli. A reaction of this kind was much more likely with the unsatisfactory type of pneumothorax. Dr. Ellman concluded by repeating that an ineffective pneumothorax should be instantly abandoned to avoid complications.

General Discussion

Dr. MAURICE DAVIDSON said that what had been learned from the discussion was the need for insisting that pulmonary tuberculosis was not a disease of the lung but a systemic disease with a local lesion.

Dr. NEVILLE OSWALD said that from a study of the record in English medical literature he had arrived at the conclusion that out of 1,000 cases of pulmonary tuberculosis roughly 40 would have had an artificial pneumothorax attempted at some time or other. The other 600 would, of course, include a large number of minimal cases as well as a number of far advanced. It appeared that there was a 20% improvement in the five-year survival rate as a result of carrying out artificial pneumothorax.

Dr. F. A. H. SIMMONDS said that there were two principal ways of controlling pulmonary tuberculosis by collapse therapy—namely, by a good artificial pneumothorax or a good thoracoplasty. If neither one nor the other could be done, collapse therapy should be avoided altogether.

MEDIAEVAL "LEPROSY"

In the Section of the History of Medicine of the Royal Society of Medicine on Feb. 2, with Dr. ASHWORTH UNDERWOOD in the chair, an address was given by Lieutenant-General S. WILLIAM MACARTHUR on "Mediaeval 'Leprosy' in the British Isles." At the same meeting an exhibit of engravings and of books and other objects of interest relating to leprosy was provided by the Wellcome Historical Museum.

Sir William MacArthur said that it was very difficult to determine the extent of leprosy in these islands in the past. The it existed was beyond question. But many people assume that the word "leprosy" in the past had its present meaning, whereas actually it had a multiplicity of meanings. In the first place, it was used in the strict sense of the disease leprosy as now understood. The writings of some fourteenth-century physicians included accounts of leprosy in its more characteristic forms, along with a good deal else that was difficult of identification. Unfortunately the word "lepra" became a classic medical term, and by the suggestion of the word itself, whose basic meaning in the Aryan languages was "something that peels off," a host of skin conditions associated with scales and scabs which had nothing whatever to do with leprosy were regarded as manifestations of that disease. The use of the plural "leprosy" by writers as far apart as Pliny and Lucretius, and Macaulay showed that they at least were aware of the comprehensiveness of the term.

The word "leprosy" was used also for conditions which were not believed to be leprosy even in the elastic sense of the word. It was used for diseases of animals and plants. "Mildew and rain make the grain leprosy." It was also used to describe miserable and pitiable states which had no connexion with the disease. The word "stricken" in *Isaiah* liii. 4 was translated by St. Jerome in the Vulgate as "leprosus," and John Wycliffe a thousand years later used "leprosy" in the same passage yet if St. Jerome and Wycliffe were alive to-day they would agree—perhaps the only point on which they would be in agreement—that the word "stricken" in the Authorized Version expressed their meaning exactly. To make confusion worse confounded the term "leprosy" was extended out of all measure by ecclesiastical example and precept. The patriarch Job was proclaimed a leper because of his "boil." The condition of the beggar in the parable was similarly named. "Lazarus," which simply meant "without cure," became synonymous with the imaginary disease, and survived to-day in "lazar" and "lazaret."

Leprosy Houses

The leper houses were mostly small institutions, each with its own set of rules. They brought relief to many miserable creatures, among whom there was no doubt a proportion of genuine lepers. In a recently published volume the number of leper houses in the British Isles was given as 324, of which

283 were in England. Yet some of these leper houses were mentioned once only, in someone's will, and nothing whatever was known about the institution and there was nothing to show what the testator meant. Others were called leper houses merely because of a statement to that effect made by some visiting antiquary and based solely on local tradition. Others were nothing more than almshouses. Houses established specifically for lepers were often transferred to some other purpose. Among others he mentioned St James's Canterbury, founded for 25 women lepers, the King's Commissioners in 1341 found it occupied by 25 women "glowing with health". Romney leper house was described in 1363 as 'derelict and totally desolate' because no lepers could be found to occupy it, it was repaired and used otherwise.

Armagh was best known to students of medical history as the site of the famous leper hospitals said to have been sacked in 869 by the Danes. He had examined all the Gaelic texts in which this destruction of Armagh by the Danes was recorded and there was no mention of leper hospitals in any of them. Sir William MacArthur explained that these annals were translated into Latin in the eighteenth century by Charles O'Connor, a man of wide learning but not a good Celtic scholar. O'Connor misunderstood the original text and translated an old Gaelic word for oratories by *nosocomia* (hospitals). A later writer, one Belcher, committed a further error and glossed O'Connor's *nosocomia* by "leper hospitals." Thus the story began. The "leper hospitals of Armagh" were never anything more than fantasies of the imagination.

Robert the Bruce

Sir William MacArthur went on to tell the story of Robert the Bruce, who was commonly reported to have died of leprosy, in 1329¹. On what evidence had Robert the Bruce been condemned for 600 years as a leper? There was no mention of leprosy by any contemporary Scottish historical writer. The story began on the English side of the Border and was recorded in two connexions only, first to explain Bruce's strange action in appointing Moray and Douglas to lead the Scottish army against the English in 1327, and secondly to account for Bruce's death about two years later. The earliest mention of leprosy occurred in *The Chronicon de Lanercost*, the work of an unknown Franciscan monk of Carlisle. It explained that Bruce appointed Moray and Douglas to command the campaign "because he had become a leper". But Bruce was absent from this campaign not because of leprosy or any other disease but because he had gone on a secret mission to Ireland. Later he returned and carried fire and sword all over the North of England. Bruce's health was failing, but there was no question of his retirement, nor did anyone shun his company. Three weeks before his death he was carrying out State business in public, and when the end was near all his lords were summoned and, surrounded by them, he closed his days in gracious state, to use the words of a Scottish chronicler.

Bruce's long feud with the Vatican was interesting in this connexion. Bruce and all his adherents were excommunicated by Clement V. Two cardinal legates were sent by a later Pope, and when they attempted over Bruce's head to publish a bull proclaiming a truce their messenger, with Bruce's concurrence, was stripped naked and the Pope's bull torn in pieces. Bruce was denounced thrice daily in every Mass excommunicated, and put under interdict, but he continued to defy the Pope. *His enemies called him by every ill name, but "leper" did not appear among the epithets.* Had Bruce suffered from leprosy or any disease that could have been termed leprosy, would not this 'judgment' have been proclaimed in every church in Christendom?

It was often said that leprosy disappeared from England owing to the strict isolation that was enforced. But there was little evidence of any form of strict isolation. The custom of regarding the leper as one dead and deprived of civil rights was never followed in England. There was no contemporary evidence that the so-called "leper windows" in churches had anything to do with lepers. "Leprosy laws" proved to be extracts from the rules of one or other of the leper houses, having no authority outside the walls of the institution. Lepers had a

¹The current *Encyclopaedia Britannica* states "Bruce died of 'pross'"

legal right to beg. In some places they could help themselves to food exposed for sale in the market place. At Shrewsbury they could take a handful of grain from every sack offered for sale. If a man did not mind being called a leper his livelihood was assured.

He was not arguing that there were no lepers, only that no statement implying the disease as now understood should be accepted unless clinical data were given to point the diagnosis. In general the diagnosis was made by monks, friars, or parish officials. If such functionaries carried out a "leper hunt" in London hospitals to-day they would not come away empty-handed, they would find chronic and intractable skin diseases, ulcerations, and deformities which would fit in with their conception of leprosy.

SIR LEONARD ROGERS, SIR PHILIP MANSON BAEHR, SIR ARTHUR MACNALTY, and others participated in a brief discussion.

Correspondence

Whither Tuberculosis?

SIR—May I replv shortly to this correspondence and comment on Dr C O Staff's brass paper, 'Tuberculosis at the Crossroads' (Feb 5, p 207), and the leading article in the same issue (p 226)? First a slight emendation as to the fate of decisions of the new Standing Committee on Tuberculosis. These are to go to the Minister and to the Central Health Services Council—presumably as the Minister directs—and not, as could be implied in my letter (Dec 25 1948, p 1118), only to the Central Health Services Council.

Dr. S Vere Pearson (Jan 22, p 152) writes he does not understand the sentence, 'Tuberculosis, environmental and clinical, now merges into a general medical directive' The delightful rural position of independent Mundesley in a far corner of a minor county makes the change from county council and county borough administration to joint hospital boards centred in university towns of no great moment. Not so, however, for the vast majority of tuberculosis workers. They now find 'directives' not from a public health committee but from academically minded regional hospital boards.

My fellow-Liverpudlian's most valuable paper, "Tuberculosis at the Crossroads," needs no embellishment. His conclusions are sure and sound, and support the foundation of the old Lancashire scheme summed up in the words, "Find, isolate, educate, treat, and rehabilitate the adult positive case." Of course everything depends on how these mere words are translated into practical measures. Thus "find" had to cover teamwork, beds for senior T.O.s, x-ray plants, whole time capable health visitors, so that out of all these things there came, most important of all, cordial co-operation from all the general practitioners. Is it at last seen how absurd was the development of the *part-time* tuberculosis officer?

I agree whole heartedly with Dr Stallibrass's conclusions as to massive infections in the first page of his paper and would draw special attention to his paragraph on the segregation of infective cases. He does not refer to *The Fate of Young Children in Tuberculous Households*¹. In 1929 the Joint Tuberculosis Council published this report of an inquiry conducted by Lancashire county borough and county council tuberculosis officers. Their third conclusion was to the effect that "the death rate from non-pulmonary tuberculosis of children exposed to risk in tuberculous households from an adult with positive sputum was

nine	times greater than the control in age group 0-1
fourteen	" " " " " " " " 1-2
nineteen	" " " " " " " " 2-5

The deaths were due mainly to tuberculous meningitis."

Your leading article, 'Co-ordination of the Tuberculosis Services' (Feb 5, p 226), sums up well and truly the present position. But what are we to do? How can we maintain the essential integration of prevention and treatment now that the National Health Act has separated them? Who will put Humpty Dumpty together again?

The Leeds Region is, I understand, trying a way to avoid the fatal divorce. Two important unifying principles are at work there. First, the chairman of the tuberculosis advisory panel of the region is the most *un*-specialized tuberculosis worker possible—namely, a T.O. holding a university teaching post for medical students and having experience and interest in prevention. Secondly, the staff of the region are under one paymaster (i.e., no joint appointments and two masters), and the field of work given to each member of the region's staff, covering diagnosis, treatment, rehabilitation, and particularly prevention, is apportioned by the tuberculosis advisory panel.—I am, etc.,

Church Stretton, Salop.

G. LISSANT COX.

Co-ordination of the Tuberculosis Services

SIR,—Your leading article (Feb. 5, p. 226) on the tuberculosis service is timely. As a social disease tuberculosis is responsible for a greater loss of man-power than any other pathological condition, and during the Hitler war for every two men from this country who were killed in action a third person died at home of this disease. Surely then the control of such a disease warrants the prime attention of those responsible for organizing the future health services of this country. Yet, as Dr. G. Lissant Cox has pointed out (Dec. 25, 1948, p. 1118), the Central Health Services Council has on it no tuberculosis specialist. Perhaps this would be excusable if it were that we knew so little about the disease that no special measures for its control were practicable, but nearly thirty years ago Sir Pendrell Varrier-Jones declared that there was no disease capable more easily of prevention than tuberculosis, and it is half a century since King Edward VII asked the famous question, "If preventable, why not prevented?" and since then considerable progress has been made towards that goal.

It has been put forward that tuberculosis officers are wanting to treat patients. It should not be forgotten that most tuberculosis officers in this country to-day are probably seeing from 25–50% more new patients each week, keeping under surveillance many more minimal cases, and maintaining far more collapse measures than ever they were before the war. Why then should they be seeking to extend their activities even further? Surely because they are more acutely aware of waiting-list problems than any other worker in the tuberculosis field, and some of us wonder whether valuable sanatorium beds really need to be occupied for such long periods by individual patients when, with modern knowledge widening rapidly the range of treatable cases, it is becoming essential to treat more and more patients somewhere.

Few would dispute the dictum of Sir Robert Philip which you quote, that the centre of tuberculosis control must be in the old dispensary, but it must not be overlooked that modern developments require much greater skill and knowledge from the tuberculosis officer than formerly. No longer does it suffice to diagnose advanced phthisis with the stethoscope and microscope; he must be a competent radiologist as well as clinician, and responsible for diagnosing all forms of chest disease, not merely phthisis. No longer does after-care comprise recommending extra nourishment for the poor and needy; the chest physician must be competent to maintain a delicate pneumothorax (or two of them) for several years, and he must be acquainted with industrial and social conditions, enabling him to advise the D.R.O. in the important field of rehabilitation. And it is to be hoped that some day B.C.G. will extend his field yet further.

If progress is to continue toward the abolition of tuberculosis (which was the aim of the old Welsh National Memorial Association), then the status and remuneration of the new "chest physician" must be such as will attract men competent to prosecute such a campaign vigorously, regardless whether they attack the disease inside or outside institutions or whether their prime interest is in differential diagnosis, collapse therapy, or social medicine. There is ample room for all. But this alone will not suffice: there must be good generalship, and at least at regional level, if not national, clear co-ordination of all aspects of tuberculosis control is essential.—I am, etc.,

REED—

W. H. TATTERSALL.

Mantoux-negative Nurses

SIR,—In his valuable paper, "Tuberculosis at the Crossroads" (Feb. 5, p. 207), Dr. C. O. Stallybrass states, "I do not think any responsible person in charge of a hospital admitting patients suffering from tuberculosis can be happy about present conditions under which Mantoux-negative nurses . . . come into contact with infectious cases."

You have from time to time published letters from me about risks to Mantoux-negative nurses, but as the last appeared over four years ago, and as such staff are still employed in nursing the tuberculous, I should like the opportunity of briefly re-expressing these views. They are based on a not inconsiderable experience with Mantoux-negative student nurses at this hospital and on the evidence in the world literature, especially that from Scandinavia, which provides overwhelming evidence that in a comparable environment Mantoux-negative persons have a far higher morbidity from tuberculosis than Mantoux-positives.

A few years ago the L.C.C. became impressed with these facts and arranged that no Mantoux-negative nurses should work in the tuberculosis wards of their general hospitals or in their tuberculosis hospitals, but they were not excluded from their sanatoria. Tuberculosis institutions in this country would appear to be divisible as regards this problem into three categories: (1) There are many in which nurses are not Mantoux-tested and "ignorance is bliss." (2) Institutions in which nurses are Mantoux-tested and carefully followed up by regular x-ray and routine examination, as recommended in the Joint Tuberculosis Council report. This is good so far as it goes, but this procedure, dictated as it is by the pressing need for nurses, does not protect them from infection. (3) A few institutions do not employ Mantoux-negative nurses in their wards.

An attempt has been made to differentiate between tuberculosis hospitals and sanatoria, chiefly by medical superintendents of the latter, in regard to the risks of infection in both. Apart from the fact that this distinction has become less and less obvious with the increasing use of collapse therapy and chemotherapy in all institutions, it must surely be recognized that wherever positive-sputum cases are treated the risk of infection is present.

When B.C.G. is available in this country, as it shortly will be, it is to be hoped that there will be a definite directive, both to general hospitals and to all institutions nursing positive-sputum cases, to urge this protective vaccination on Mantoux-negative nurses.—I am, etc.,

Colindale Hospital, London, N.W.9.

W. E. SNELL.

Tuberculous Infection of Infants

SIR,—In Dr. C. O. Stallybrass's article, "Tuberculosis at the Crossroads" (Feb. 5, p. 207), the work of the maternity unit at Black Notley Hospital is mentioned (p. 211), but the presentation of figures of infant morbidity may give rise to an erroneous impression.

It is true that in an early follow-up of infants the morbidity figures of those born to mothers remaining sputum-positive was 4 out of 11. We must point out that these figures related to those mothers who remained sputum-positive after discharge, and no infants were infected while in the unit. It is true also that 2 of these 4 died, but the other 2 developed only mild glandular infections and recovered. A follow-up, shortly to be published by one of us (M.C.W.), of a large series of infants and children treated at Black Notley for tuberculous lymphadenitis confirmed that this is a benign form of tuberculosis, and that a primary infection occurring in a child born of a tuberculous mother is not necessarily of evil consequence.

The series quoted was a small one, and an investigation of the larger numbers now available is proposed, but we have no reason to believe that the incidence of serious tuberculous infection in infants born in the unit is likely to be high. Dr. Stallybrass must be unaware that, though the conditions in the maternity unit are excellent, the infants reported on were in many cases discharged to the Greater London area under war-time conditions.

At the same time, although we feel that the dangers of familial infection of infants can easily be exaggerated, we would like to agree most whole-heartedly with Dr. Stallybrass that vaccination with B.C.G. of infants exposed to contact infection is

desirable as a promising means of reducing the incidence of tuberculous disease, however small it may be without that protection.—We are, etc.,

Braintree, Essex.

M. C. WILKINSON.
RAYMOND C. COHEN.

Spinal Anaesthesia for Caesarean Section

SIR,—It should be a *sine qua non* that those who desire to criticize any procedure, whether medical or surgical, should be sure of their facts and up-to-date in their knowledge of the relevant literature, and that their strictures should be supported by personal experience. The use of spinal anaesthesia for caesarean section has been the subject of far too much ill-informed criticism in the past.

Among the severest critics of spinal anaesthesia in pregnancy have been the late Dr. Joseph B. DeLee, founder and for many years head of the Chicago Lying-in Hospital, and Dr. J. P. Greenhill, DeLee's successor at the same hospital. The well-known *Year-Book of Obstetrics and Gynecology*, in which much of the criticism has appeared, has been edited by DeLee and Greenhill.

The main object of my letter is to place on record what I consider to be one of the most significant milestones in the course of the controversy about spinal anaesthesia in pregnancy. In October, 1948, I received a letter from Dr. George J. Andros, assistant professor of obstetrics in the Chicago Lying-in Hospital, which I think should be published in full.

"I have been intending to write you for a long time to commend you on your splendid work in championing the cause of spinal anaesthesia in obstetrics. Your efforts have made a great impression upon those of us who seek to further the use of this method in America. You might be interested to know that at the present time in the Chicago Lying-in Hospital approximately 85% of all caesarean sections are done under spinal anaesthesia (primarily continuous spinal) and over 50% of the vaginal deliveries are carried out under spinal (saddle-block) anaesthesia. You probably realize that this is quite a departure from the teachings of our founder, Dr. Joseph B. DeLee.

"My immediate purpose in writing you at this time is to ask whether or not it would be possible for me to obtain from you a copy of the entire text of the "Discussion on Anaesthesia for Caesarean Section" appearing in the *Proceedings of the Royal Society of Medicine*, August, 1947. If you do not have this material at hand, can you direct me to the proper source? I wish to use the material presented in this discussion as reference for publications and lectures on spinal anaesthesia in obstetrics.

"Incidentally, we have done approximately 35 caesarean sections with 'heavy nupercaine' in doses of 2.5 mg. and 3.75 mg."

The significance of this letter, coming as it does from the assistant professor in Dr. Greenhill's own hospital, will not, I hope, be overlooked by those (and there are many) who have in the past criticized the use of spinal anaesthesia in obstetrics and more especially for caesarean section.

There is not the slightest doubt that spinal anaesthesia in some form or other (single dosage as used by me and many others, or continuous dosage as indicated by Dr. Andros) has established itself as a safe anaesthetic "for suitable cases" in obstetrics. There are of course certain contraindications, such as low blood pressure, shock, recent severe blood loss, and severe anaemia, to which I have never failed to draw attention in the various articles which I have written on the subject. But in many instances these contraindications can be eliminated and their dangers removed by blood transfusion and the use of hypertensive drugs, of which the best is undoubtedly *d-N-methylamphetamine hydrochloride*, and oxygen.

Finally, may I express the hope that those who have no personal experience will withhold criticism until they have taken the trouble to acquire the technique and tried it out for themselves, with, of course, the proper precautions?—I am, etc.,

Croydon.

RUFUS C. THOMAS.

Classical Caesarean Section

SIR,—In my condemnation of classical caesarean section I have been accused of using harsh words. I can only say they were deliberately chosen: only so could I hope to influence 'those who frequently practise' the operation. What is grievous, however, is that some of my colleagues have misread my letter (Oct. 16, 1948, p. 722) and so have objected to opinions

which I never stated. Just as for any operation, so for the classical caesarean section there are indications, some definite, some debatable; and I should now like to formulate these as my main contribution to the controversy and at the same time to comment on some interesting points which have been raised.

Definite indications for upper-segment caesarean section

1. The presence of a large cervical fibroid can obliterate the lower part of the cavity of the uterus to such an extent that it may be difficult to find the cavity, let alone deliver the foetus, if the uterine incision is placed low. In such cases an upper-segment incision must be performed.

2. Shoulder presentation in which the liquor has drained away and the uterus is tightly moulded round the foetus: in such a case a low vertical incision, which can be enlarged upwards if necessary, should be employed. This is the type of case described by Mr. Percy Malpas (Jan. 22, p. 156). In the most extreme example of the condition that I have seen the foetal elbow had prolapsed into the vagina through a cervix half dilated, and there was such a marked contraction ring round the arm and forearm that they were grooved by it: replacement of the foetus was quite impossible even under general anaesthesia. To deliver the child I used a vertical uterine incision, half in the lower and half in the upper segment.

3. Where there is a contraction ring requiring incision.

4. In certain dwarfs with little room between costal margin and symphysis pubis, and where the uterus fills the whole abdomen: access to the lower segment may then be very difficult.

Other conditions for which classical caesarean section may be indicated

1. When the lower segment is so narrow and ill-formed that there is not room in it for an incision large enough to deliver the child through—e.g., transverse lie in a uterus bicornis unicollis in a primigravida patient. In such cases a low vertical incision should be employed: this may be made partly in the lower segment if the bladder is pushed down first.

2. In certain cases of fibroids lying in the upper segment when they are to be removed at the time of the caesarean section.

3. Cases in which as a result of previous operations there are extensive adhesions between uterus and abdominal wall. In such cases the uterus should be opened in some readily accessible place. Caesarean section following previous ventrifixation of the uterus may come in this category. I have only operated on one such case, and rightly or wrongly freed the uterus from the abdominal wall and performed a lower-segment caesarean operation.

4. In cases where there are large blood vessels coursing across the lower segment and when the surgeon is inexperienced or anxious about the outcome of a low incision, an upper-segment incision is probably the lesser of evils. This is the type of case my namesake, Mr. P. M. G. Russell (Oct. 30, 1948, p. 798), refers to. In my experience these blood vessels do not always cause as much trouble as one expects. A tip of real value if bleeding threatens to be troublesome is to complete the incision by tearing rather than by cutting; this puts the edges of the uterine incision on the stretch and so closes the opened sinuses until they can be deliberately grasped with Green-Armytage or other forceps.

5. I am reluctant to accept Professor S. J. Cameron's claim (Nov. 27, 1948, p. 956) that classical caesarean section should be chosen "when rapid delivery is indicated." Emphasis on speed in midwifery is not without its dangers—to foetus as well as to mother—so I should prefer the advice "hurry slowly"; perhaps then the lower-segment caesarean section will be judged quick enough.

I agree whole-heartedly with Professor W. C. W. Nixon (Oct. 30, 1948, p. 798) in his plea for the low incision in abdominal hysterotomy; I have used this approach for some years and am sure it is generally preferable to the more usual high incision. A possible exception is the woman who is being operated on under local anaesthesia; access to the lower segment is then not easy.

Dr. Guy Roworth (Oct. 30, 1948, p. 798) suggests that in certain cases the vertical incision half in lower segment and half in upper segment is superior to the transverse incision in lower segment. I do not have enough knowledge of the late effects of what might be called the "half-and-half" incision to make any comments on this comparison. I hope others will feel able to give their experience on this subject.—I am, etc.,

Manchester.

C. SCOTT RUSSELL.

SIR.—I was interested to read Mr. Percy Malpas's letter on caesarean section (Jan. 22, p. 156) and the difficulties that he had encountered in delivering an impacted shoulder presentation by the lower-segment route. I have personally encountered five cases in which I had difficulties similar to those described by Mr. Malpas. Three of these were cases of impacted shoulder presentation and the other two were vertex presentations associated with severe kypho-scoliosis. In one

of the latter cases the patient was a severely dwarfed hunchback, and in the other the patient herself had been born with a spina bifida from which she had survived but which had left a severe pelvic deformity. In both of the latter cases pelvic measurements taken by x-ray pelvimetry were extremely small.

In the case of the shoulder presentations I encountered exactly the same difficulty as Mr. Malpas describes—namely, that it was nearly impossible to bring the babies' legs down the lower-segment incision without tremendous strain on both the foetal trunk and the uterine muscle. In the other two cases I found that the pelvic deformity was such that it was extremely difficult both to elevate the foetal head and at the same time draw it anteriorly into the uterine incision.

In each one of these five cases I found that the solution was to convert the transverse incision in the lower uterine segment into a T-shaped incision. This was carried out simply by incising the lowest part of the upper segment vertically from the middle of the transverse lower-uterine-segment incision. The length of this second incision was in each case about 3 in. (7.5 cm.), but I found that on completing the operation, and with full retraction of the uterus, this 3-in. incision now measured only about 1 in. (2.5 cm.). All that was then required was the insertion of one or two stitches into the vertical incision, followed by closure of the transverse lower-segment incision in the usual manner. It was quite simple to overlap both incisions with the reflection of peritoneum which is raised as a routine in performing lower-segment caesarean section. The resulting convalescence was excellent in all of these patients.—I am, etc.,

London, W 1

D. G. WILSON CLYNE.

Anaesthesia in Ludwig's Angina

SIR,—Dr. V. Torry Baxter, referring to my letter (Jan. 1, p. 31), has written (Jan. 22, p. 153) an able account of the considerations involved in anaesthetizing cases of this disease in which there is severe obstruction to breathing, but he goes on to state that to induce unconsciousness as a preliminary to surgical intervention in cases of Ludwig's angina is to court disaster. Whilst agreeing with this statement when it is applied to cases with severe respiratory obstruction, I am convinced it is not true of all cases.

By no means all cases of Ludwig's angina are complicated by respiratory obstruction: indeed, most of the cases that come to operation are breathing normally, while some are only obstructed to a minor degree. If Dr. Baxter's statement is true, halothane has for many years been courted with the aid of chloroform and, more recently, cyclopropane, with what can only be described as a very indifferent response. If, however, there is anyone who would wish to see this courtship fairly crowned with success, let him try induction with "pentothal" on a few of these cases. He will not have to wait long before his wish is abundantly fulfilled.

Mr. Eric K. Gardner (Jan. 22, p. 153) raises a point which will be generally agreed. Junior residents should not be expected to undertake this responsibility. If they were aware of the dangers involved they would doubtless more often enlist the help of their seniors. But as long as intravenous anaesthesia continues to be recommended for this operation in the latest surgical textbooks one can hardly blame them for administering it, and can only sympathize with them and the relatives when the results are disastrous.—I am, etc.,

Sutton, Surrey

JOHN H. WILLIS.

Bronchography without Surface Anaesthesia

SIR,—Anaesthesia for bronchoscopy and gastroscopy is undoubtedly necessary, and it may therefore be essential to use one of the more potent but toxic surface anaesthetics in cases requiring these procedures. However, Mr. C. A. Jackson in his article on amethocaine hydrochloride (Jan. 15, p. 99) and, more especially, Dr. C. Elaine Field in her letter (Feb. 5, p. 236) advocate the use of amethocaine hydrochloride in bronchography.

When bronchography is done by the cricothyroid-membrane route it has been common practice to inject some potentially dangerous surface anaesthetic through the needle into the trachea before the contrast oil is instilled. In an attempt to avoid the use of any member of this group of drugs, I and

others have done many successful bronchographies in adults without the use of any intratracheal surface anaesthesia. Coughing and discomfort are no more than with anaesthesia, which must always be very limited in view of the small bulk of fluid used. Procaine is, of course, used to infiltrate the skin and subcutaneous tissues over the membrane before the introduction of the needle.

I would therefore urge the abandonment of the use of any of the surface anaesthetics in bronchography. Let it be remembered that over a thousand years ago, in the *Guide to Physicians* by Isaac Judaeus, appeared the aphorism, "Treating the sick is like boring holes in pearls, and the physician must act with caution lest he destroy the pearl committed to his charge."—I am, etc.,

Liverpool

EWAN F. B. CADMAN.

Proguanil and Blackwater Fever

SIR,—In view of the recent letters on proguanil ("paludrine") I thought the following case might be of interest.

A young European was brought to hospital who had been comatose for 18 hours; blackwater fever was diagnosed, but despite treatment he died within 12 hours. This patient had been in the country some 15 months, living most of that time in the bush in a highly malarious district. For the whole period he took one tablet of proguanil every alternate day regularly. He had also been in Egypt for a short period before coming to Uganda. He had never suffered from malaria nor from fever of unknown origin, and he had never taken quinine at any time until this illness.

Before coming to hospital he had received treatment for clinical malaria in his bungalow—quinine bihydrochloride 30 gr. (2 g.) on three successive days. He was admitted to hospital on the fourth day of the disease.

From experience we have found that anything less than one tablet of proguanil a day will not suppress malaria. There have been several cases where the person was taking one tablet on alternate days regularly, yet they developed a typical attack of malaria with a positive blood slide (subtertian). It is presumed that the case reported above was in fact blackwater fever from the onset; if so, was it precipitated perhaps by the fact that proguanil was acting as an insufficient suppressive on the malarial parasites?

I am indebted to the D.M.S., Uganda, for permission to publish this report.

—I am, etc.,

Mbale, Uganda

A. M. BEST.

Strong Corsets and Pelvic Congestion

SIR,—During the past two years I have observed a group of 32 cases of women who have reported either at my consulting-rooms or the out-patient department with the symptoms of pelvic congestion. These took the form of backache, bouts of urinary frequency, fullness in the rectum, iliac-fossa aching, and general pelvic dragging. All these symptoms might appear together or singly, or in one or other combination.

The ages of these patients ranged from 22 to 42 years. A feature common to them all was that they had obese abdominal walls with very firm fat. Cystoscopy revealed on several occasions that the vessels, especially the veins of the trigone, were obviously more congested than normal (this was during the period of urinary frequency). When iliac-fossa aching appeared to be confined to one side it was more frequently noticeable on the right than the left side.

The second noticeable feature was that the patients' symptoms in this group dated from the acquisition of good, strong surgical corsets. Previous to the use of these strong, well-fitting corsets, which no doubt did mould the patient's figure in an approved fashion, this group had used what they considered loose utility supports. It was noticeable that this firm fat, presumably due to a high carbohydrate diet, had been deposited freely in the abdomen because there was no real pressure on this area to induce it to be deposited elsewhere (shoulders, breasts, thighs). I assumed that these strong corsets were compressing this firm fat against the inferior vena cava and impeding the venous return from the lower limbs, with stagnation in the pelvic veins or right ovarian veins. I asked these patients to either dispense with corsets for a month or wear them loosely. The improvement in the patients' symptoms

was definitely established; by wearing their corsets more loosely applied thereafter these patients very definitely improved or were free of symptoms without further therapy.

There are two other groups of cases which fit into a similar picture but of which I have not had sufficient cases with such definite reference in order to link them with the above. The first group consists of young women with long lower limbs beginning to wear a high-type girdle. These develop backache or right iliac-fossa aching, presumably due to abdominal constriction at the umbilical level. It would seem that by the time the blood from the lower limbs reaches the pelvis the *vis a tergo* is sufficiently low to permit stagnation in the pelvic or ovarian vessels (10 cases). The second group were elderly women who began to develop a progressively worse prolapse, also suggestively dated from the acquisition of strong corsets and abdominal compression (9 cases).

I would advise that corset manufacturers should warn their fitters that where the patient has not been accustomed to strong abdominal support corset fittings should be so applied that the abdominal compression can be increased gradually over a period of months, so as to obviate this syndrome developing—I am etc.

LINDSAY O WATT

Prescription of Barbiturates

SIR—I was greatly interested in Dr. Nathan Finn's letter (Jan 29, p. 195) regarding the prescription of barbiturates, as this problem has occupied my mind for some time. The idea of combining phenobarbitone with an effective emetic in the same tablet presents itself quite obviously, but the solution is not as simple as it appears to be.

From theoretical and practical considerations we have to include the optimum emetic dose (e.g., *pulv. ipecac.* which is the only drug suitable for the purpose) into the minimum lethal dose of phenobarbitone. The M.L.D. of phenobarbitone is 5-6 gr. (0.32-0.4 g.),¹ and the emetic dose of *pulv. ipecac.* is 15-20 gr. (1-1.3 g.). This means that every $\frac{1}{2}$ -gr. (32 mg.) tablet of phenobarbitone will contain nearly the maximum expectorant dose of *pulv. ipecac.* with all its irritant properties—a quite undesirable feature.

Secondly, it is most important to remember that phenobarbitone, being absorbed simultaneously with *pulv. ipecac.* (probably at an even faster rate), will neutralize the vomiting effect of the latter by virtue of its own sedative properties. In practice the patient will be dead before he is "due" to vomit.

I see the solution of this important problem not in the combination of barbiturates with emetics but in avoiding prescribing these drugs to a phenobarbitone-conscious public and in the choice of other sedatives wherever possible. The open-chain ureides, like carbomal, etc., are fairly safe and generally not much less effective alternatives—I am, etc.

Cogs in a Machine

SIR,—With reference to the "health records" for this country in 1948, I should like to point out that it is absurd for us to congratulate ourselves upon the better health of the nation when arguing only from those figures which relate to physical well-being. There are no statistics available to give an adequate picture of the nation's health over the whole field—in, that is to say, its physical, mental, and psychological condition. Yet the human being is a threefold entity (body, mind, and spirit), each part of whose nature is intimately related to the other.

Most medical practitioners are becoming uncomfortably aware of the increasingly high incidence of psychological and psychosomatic conditions. Not only are positive personality disorders on the increase; very many people are exhibiting symptoms whose ultimate origin is psychological. Even where this is not the case, increasing numbers of people are becoming subject to irritability, disproportionate anxiety, and apparently unreasonable feelings of insecurity, which, while realizing their insufficient foundation, they find they cannot control.

To no small degree the reason is to be found in our machine civilization, which turns the individual into a cog in the industrial or military machine. This procrustean bed, to which each one of us in our proud individuality has to be

lopped, is proving very uneasy. The natural revenge is an increasing number of cases of derangement of the nervous system.

In this country, even to-day, there is a tendency to confuse the treatment of the disordered psyche with the treatment of the disordered brain. For the sake of the millions to whom the pressures of modern life have brought abnormal stress this attitude should be modified. The effects of machine civilization should be investigated and the conditions of life and work adjusted to human needs. This is all the more necessary because in the field of physical health our average of attainment is rising. Personality disorders and psychic conflicts are handed down from one generation to the next, not according to laws of heredity as in the physical sense, but according to laws of stress and reaction—maladjusted parents producing maladjusted children.

There is in English public life an extraordinary tendency to close the eyes to the fact that human health and human happiness cannot be attained by concentrating only upon one aspect of the human being. Although more sensible diet and more advanced discoveries in the realm of therapeutics have helped to improve our general level of physical health, that still gives us only one part of the picture. Moreover, if the mental and psychological well-being of the people is overlooked, it cannot be long before their physical health suffers too.—I am, etc.

Malignant Tumour of the Small Intestine

SIR,—While awaiting a proof of the report on jejunal carcinoma (Feb. 12, p. 283) I wanted to add a few rather vital words to one sentence. Where it says in the penultimate paragraph "ulcer of finger-tip size in the lower curve of the stomach," please add, "No abnormality was noted in the jejunum"—I am, etc.

Bristol

A WILFRID ADAMS

POINTS FROM LETTERS

Dental Caries

Dr WILLIAM WALLACE (Glasgow) writes: A novel but neglected solution of the dental caries problem may be referred to in the *Transactions of the Royal Medico-surgical Society of Glasgow* (1933, 27, 217). I might now allude to the study of the comparative rate of the incidence of dental caries in the teeth of three groups of five-year-old children by Lady Mellanby and her colleagues (May 31, 1947, p. 751); they admit that they have failed to discover the direct or immediate excitant of this disease and also that there is "an anomalous" freedom from caries in teeth of defective structure in institutional children. They now wish to know why and how this is so, and state: "If there are secrets yet to be discovered which can explain these results, as there almost certainly are, every effort should be made to reveal them." This disease is virtually pandemic. It is what may be called a primitive one—i.e., one due to the absence of something the teeth cannot do without (namely, daily use) lest they contract a microbic rust—when from nausea or loss of appetite mastication becomes interrupted for a day or more, during which time the ameloclast seizes the opportunity of affixing itself in an interstice between two teeth or a fissure in a premolar or molar. Anticipation of decay in the second molars is the key to the prevention of dental caries.

The Crisis in Lobar Pneumonia

Dr L. R. HOLT (Stamford, Lincs) writes: The history of the following case of lobar pneumonia, which had no treatment with the "sulpha" drugs, seems to be worthy of record. I was recently called out to an ex-R.A.F. camp near here, which is now occupied by "squatters," to see a girl aged 6½ years about whom the mother gave the following story. Eight days prior to my visit the little girl had been seized with sudden pain in the left chest, accompanied by high fever, dry cough, and vomiting. As it was a Sunday and the parents did not wish to disturb the doctor on the Sabbath (how rare in these days of the new N.H.S.) they deferred until the next day. But she seemed a little better on the Monday, and so they hung on, day after day, until on the evening of the seventh day the child became delirious, sweated profusely, and was apparently exhausted. I was summoned for the first time on the following morning, and on examining the child found signs of consolidation of the lower lobe of the left lung consistent with lobar pneumonia: the temperature was 98.6° F. (37° C.), respiratory rate 40, and the pulse rate 120. Employing conservative measures, she made an uninterrupted recovery. How many of the younger generation of doctors have witnessed the "crisis" of lobar pneumonia, which this girl undoubtedly exhibited on the evening prior to my first visit? It must be a rare clinical experience in these days of penicillin and the "sulpha" drugs.

Obituary

H. D. HALDIN-DAVIS, D.M., F.R.C.P., F.R.C.S.

The death of Dr. Harold David Haldin-Davis, at Forest Row, Sussex, on Feb. 2, so closely following that of Dr. J. H. Sequeira, has robbed British dermatology of yet another outstanding figure. Dr. Haldin-Davis was 67, and for the past three years had borne with great fortitude the painful complications of a disease which he well knew to be incurable and ultimately fatal.

Educated at Charterhouse, he won a scholarship at Balliol College, Oxford, and took his B.A. with first-class honours in physiology. At St. Bartholomew's Hospital his preference seems to have been surgical at first, for in 1908, three years after graduating B.M., B.Ch., he added the F.R.C.S. to his other qualifications. Shortly afterwards he passed the examination for the M.R.C.P. About this time, too, under the tutelage of Dr. Adamson, one of the foremost dermatologists of the day, he began to take an interest in dermatology, and made it his special study. He read extensively, and with a rare memory for facts and figures would frequently flavour both his lectures and writings with classical and literary quotations. He passed without apparent effort all the examinations he ever sat for. In 1925 he proceeded M.D., and he was elected F.R.C.P. in 1931.

Haldin-Davis dedicated most of his professional life to the dermatological department of the Royal Free Hospital, where his fluent, witty, and discursive lectures won him a host of admirers and friends. He was equally popular at the Blackfriars Skin Hospital, and his influence there and the high standards he set enlarged its field of work and attracted many postgraduate students. But these activities and an increasing private practice did not satisfy him. He became the visiting dermatologist to the Children's Hospital at Paddington Green, and for many years he supervised the Willesden clinic for the treatment of ringworm of the scalp by x rays. This and other pioneer work was undertaken before the outbreak of the 1914-18 war. As a Territorial officer he served in the R.A.M.C. and saw active service in Palestine. In 1918 he took up his ordinary routine again and assumed an additional appointment as specialist in dermatology to the Ministry of Pensions.

Although he worked so hard, "Hal," as he was known to his friends, found time for social occasions, and his hospitality, ably furthered by his wife, both in town and country, became proverbial. But still it was not enough. He assumed civic duties, became a councillor, and was well in the running for the mayoralty of St. Marylebone. He had a fund of kindly humour, and his wit, though pungent at times, was always under control and seldom malicious. He was a great admirer of Dr. Johnson and a member of the Johnsonian Society.

He was secretary of the Dermatological Section at the annual meeting of the B.M.A. in 1922, and a vice-president in 1927 and again in 1929. Many reviews, annotations, and articles in this *Journal* came from his pen for more than twenty years. His handbook on *Skin Diseases in General Practice* reached a third edition in 1937. In the same year he became president of the Dermatological Section of the Royal Society of Medicine, where he had always been a frequent exhibitor of rare cases and an eloquent speaker at discussions. This office was admirably suited to his critical temperament and his natural and highly trained faculty for conducting meetings and committees. Haldin-Davis thoroughly enjoyed his two years as president, and particularly those occasions which required the kind of after-dinner speech at which he excelled. His polite cynicism, liberally adorned with appropriate quotations and anecdotes, enlivened many a dull dinner in those pre-war days.

Haldin-Davis was a born critic. Ever suspicious of new theories and sceptical of vaunted specifics, the old adage, "Make haste to apply this new remedy while it still cures," was frequently on his lips. But he was severely critical of himself too, and this attitude may account for the scarcity of dogmatic assertion and speculative theorizing in his literary work. Research was not in his line. He had neither the patience nor the aptitude for it. On the other hand he was

an extremely able man of business, and his sage advice on matters of finance was constantly in demand and was freely offered to many relatives and friends. His health had begun to fail even before the recent war, but in spite of his disabilities he continued to give his services to local hospitals, and helped to guide committees at Tunbridge Wells and East Grinstead. He also inaugurated a most successful War Savings group in the same area. His last official medical appointment was that of medical referee to the Ministry of National Insurance. All his many friends and colleagues will join in offering their sympathy to his widow and two stepchildren. His was a unique personality, and none who knew him well will ever cease to cherish his memory.

SIR EDMUND SPRIGGS, K.C.V.O., M.D., F.R.C.P.

A colleague writes: Sir Edmund Spriggs was best known, both to his medical colleagues and to a large circle of patients, by his association with, and development of, the Clinic now at Ruthin Castle. Here he had the opportunity for the intensive and detailed study, and also the controlled treatment, of most types of disease and particularly the metabolic and digestive ailments for which his earlier work in London had prepared him. Success in this field was recognized by his election as president of the Gastro-Enterological Society in 1947, of which society he was also a foundation member. Spriggs was above all a clinician. He was quick to receive new ideas, provided he thought that they were founded on sound physiological principles. Thus insulin was prepared at the clinic and used under his supervision in early 1923, but he always maintained that diet must still play an important part in the treatment of diabetes mellitus. The new was tried out against the old, and so the introduction of the electrocardiograph did not lead to the abandonment of the well-established "stair test." He always took the broad view and treated the individual as well as the disease. This attitude of mind was combined with a meticulous attention to detail, especially where diet, rest, and exercise were concerned. The best type of book to be read by a bad sleeper before trying to settle at night was not too trivial for discussion and advice. His own long illness in earlier years had given him an insight into the mentality of the "bed patient." The same attention to detail was shown in the way articles for lectures or publication were prepared. The description which only occupied a few lines of a typical case of gastric carcinoma in one such paper was the condensed analysis of over fifty cases personally observed. For another article more than 500 follow-up letters were written to ensure accuracy in his report on the final results. When the facts were ascertained the real work began, and the alterations and emendations in the manuscript only ended, much to the relief of his secretarial staff, at the last possible moment before delivery or publication.

While accepting that art is long, he often overlooked the fact that time is fleeting, especially if engaged on a task in which he was interested; this led at times to minor embarrassments. His own description of a perfect holiday was one on which no watch was carried and bodily needs were satisfied when hunger, thirst, or tiredness dictated. On such occasions he was an interesting and entertaining companion. He read rapidly and widely and had a retentive memory; this often led to the solving of a difficult problem by reference to an article read, or a case seen, years before. Cautious in reaching a conclusion, he was a formidable opponent if his views were attacked, but always ready to abandon a position when convinced it was untenable. He was "ever a candidate for truth" and eager to find out where it was hid. This urge to get to the root of the matter was noticeable in his work as a magistrate and vice-chairman of his bench. Calm, courteous, but persistent, he probed the case under consideration, and, as a court official said, "I will always be grateful to Sir Edmund, for he taught me patience." His quiet friendliness invited personal confidences, and he received many and, as one who had seen trouble himself, "his ready help was ever nigh." It is easier to write of the physician than of the man without being suspected of exaggeration. Tolerant, wise and far-seeing in counsel, kindly and generous in word and deed, with a high sense of duty and ready to further any good cause, as evidenced by the many societies in which he held office, he met the blows of life with serene courage and without any of the bitterness that might

new prescription model
infra-red treatment lamp**

Sovereign in the treatment of injuries and infections, and 'pre-eminent in the relief of pain', infra-red irradiation is most valuable when the patient can apply it at home. This new Sollux Lamp (Model H.VI) is ideal for domestic application. It gives the maximum output tolerable for house wiring, has interchangeable luminous and long-wave sources, and embodies universal adjustments. The price is £13 10.0. A patient can purchase only on producing a certificate from his own doctor stating that use of the lamp is necessary.

For details of construction and output, see Hanovia leaflet No. M. 175 — freely sent on request.

**For children
who are growing fast**

Children who are growing rapidly and making heavy demands on energy reserves need not only the normal intake of rationed foods but also a supplementary supply of vitamins and carbohydrates to meet their high metabolic needs.

For children of all ages Radio-Malt is a desirable dietary supplement and metabolic stimulant.

Each fluid ounce contains

Vitamin A	2000 international units
Vitamin B ₁	200 international units
Vitamin B ₂	0.2 mg.
Vitamin D ₃	1000 international units
Calories 109 Protein 1.75 grammes	

Radio-Malt is available in 1 lb. and 2 lb. jars.

have soured a lesser man. That he was known to his staff as the Chief" is sufficient indication of the esteem in which they held him. It takes a big man to be a hero to his valet. 'He'll be sair missed' by all who knew him, and much sympathy will be felt for his two doctor sons in their bereavement.

Dr JOHN WATT, who died on Jan. 2 at the age of 68, was a native of Glasgow. He took the LDS there in 1904 and the Scottish triple qualification in 1913. He served in the first world war as a captain in the R.A.M.C. He then went to Skye first to Broadford and then to Portree. After five years' strenuous service Dr Watt decided to return to the mainland, and he took up practice twenty-six years ago in Muthill, Perthshire. Unobtrusive in nature and sparing in speech, he was skilful in diagnosis and endeared himself to the people by his kindly sympathy. Dr Watt took his share along with other local practitioners in the work of the Creiff and District Cottage Hospital as a member of the honorary medical staff. He was also interested in the District Nursing Association, and during the recent war was in charge of the medical side of the local civil defence organization. He was also a justice of the peace for Perthshire. He was a keen sportsman, and many owe their skill as fishermen to him. His wife died with tragic suddenness seven years ago.—E. A. S.

Dr ALEXANDER GORDON INGRAM, who died on Jan. 28 at the age of 85, had been in practice in Helensburgh for nearly sixty years. He graduated M.B., C.M. at Aberdeen in 1886, and went into general practice in Helensburgh in 1889. After taking the D.P.H. in 1913 he was appointed medical officer of health for the burgh and medical superintendent of the local infectious diseases hospital and sanatorium, he was also in charge of the child-welfare and antenatal clinics. Although he had given up his large general practice he continued active work in his other posts until a few months ago. Rather shy by nature, he was a man of wide interests but primarily he devoted himself to the care of his patients, by whom he was held in high esteem. A native of Banffshire, he had his full share of North-Country wit and had a great fund of anecdotes. Dr Ingram was chairman of the Dunbartonshire Division of the B.M.A. from 1933 to 1938. He took a great interest in the younger practitioners in the area, and he spared no pains to help and encourage them. His jubilee was marked by a public presentation from his patients and friends of an illuminated address and a cheque. When he reached his diamond jubilee he entertained his colleagues in the town to a dinner. Ingram was a man of keen intellect and genial kindness, and those of us who are left feel the better for having known him.—W. G.

Dr MAVIS VICTORIA ZANE, who died in London on Feb. 7 at the age of 52, was born in Australia and graduated at the University of Sydney. After ten years as medical officer for girls' schools under the Egyptian Ministry of Education she served in a number of English hospitals and infant and child-welfare clinics. She joined the staff of the Save the Children Fund in January, 1948, and was appointed medical superintendent of the Fund's hospital at Schlutup near Lubeck. This was a 100 bed hospital for the children of displaced persons from camps in the neighbourhood. The hospital, on the shores of the Baltic, was formerly the administrative block of a secret war factory concealed in the neighbouring woods, and the building was admirably adapted to its new purpose. Changed conditions in Germany brought about the transfer of the hospital to the German authorities towards the end of last year. Dr Zane was ill when she returned from Germany last autumn, and did not recover.

The Services

The Prince Regent of Belgium has bestowed the decoration of Chevalier of the Order of the Crown upon Temporary Surgeon Lieutenant-Commander G. F. Carey, R.N.V.S.R., for distinguished services rendered to Belgium during the war.

The King of Norway has bestowed the decoration of Norwegian War Medal upon Surgeon Lieutenant-Commander J. M. Rudyard, R.N.V.R., for distinguished services with the Royal Norwegian Navy during the war.

The Efficiency Decoration has been conferred upon Lieutenant-Colonel G. E. O'Riordan and Major E. Fowler, R.A.M.C., T.A.

Medical Notes in Parliament

COST OF HEALTH SERVICE

Supplementary Estimates

It appears that the cost of the National Health Service for its first nine months will be £58,455,000 more than was originally estimated, an increase of over 39%. This is one of the main items given in the Supplementary Civil Estimates for £221,471,574 issued by the Stationery Office on Feb. 9. For England and Wales the extra sum required is £52,800,000 and for Scotland £5,655,000.

The ophthalmic services, which were expected to cost £2,330,000, are now estimated at £14,970,000. The cost of dental services will be £21,800,000 instead of £8,150,000. Drugs, medicines, and appliances will cost £17,715,000, as against the first estimate of £12,700,000.

Payments to medical practitioners at a cost of £29,800,000 show an increase of £2,300,000. The administration of the Service will cost £1,606,000 as against £890,000.

The increase in the cost of hospitals and specialist services will be £24,446,000. The liabilities of the hospitals which were transferred to the Government on the appointed day exceeded the first calculation by £17,409,000.

These supplementary estimates are to be debated on Feb. 17, and it is expected that the debate will turn mainly on the cost of the National Health Service. It had been estimated that the Service would cost in the nine months from July 5, 1948, to the end of the financial year about £150,000,000. The supplementary estimates now before the House show that the cost for the nine months will actually be £208,000,000. If expenditure continues at this rate the cost in a full year would be £277,000,000.

Too Many Patients

Mr BEVAN on Feb. 9 informed Mr MARTIN LINDSAY that approximately 5,000 patients had been instructed by the Birmingham National Health Executive Council to change their registered medical practitioners. Later on the same day Mr Lindsay opened a debate on this subject.

He said that over 3,000 people in Solihull had been instructed by the Birmingham Executive Council to leave the doctors of their choice, whose patients they had been in many cases for a number of years. The same thing had happened all over Birmingham. On the appointed day last year a number of doctors found themselves taking over many more patients than they could hope to handle. One doctor in his constituency who had a reputation as a painstaking physician found that over 3,000 patients had registered with him beyond the figure of 4,000 laid down as a maximum. The local executive council in such cases had no choice but to ask some registered patients to leave their doctor and find another. Mr Lindsay did not question that, but questioned the method of selection of the patients who were to be removed. The fair method was to remove recent additions to the doctor's list and those people who had registered for the first time with him at the appointed date.

Another Birmingham doctor had been told that he had 500 patients in excess of 4,000 and must get rid of them by March 4 unless he obtained an assistant. The doctor had taken every possible step to find an assistant but could not do so because he could not offer accommodation to a married assistant and his family. Mr Lindsay noted that before July 5 this doctor had the same number of patients as he had now, and his practice worked smoothly. Mr Lindsay suggested that the figure of 4,000 should not be a statutory maximum but a guide to the approximate number of patients which a doctor could treat single-handed. If the patients considered they were not getting satisfactory service they could leave the doctor of their choice and go to someone else. The doctor had every incentive to keep up his list by looking after patients properly. Some doctors were quicker than others, and some had practices which were topographically more compact. He suggested that the maximum number should be left to the doctor concerned, the figure of 4,000 being merely a guide. He asked the Minister to instruct executive councils that where a doctor's list was much too large the recent additions to it should be removed and not patients who had long been attended by that doctor.

Sir PETER BENNETT said that from his constituency on the other side of Birmingham he had received similar complaints.

Replying to the debate, Mr BLENKINSOP said it was far from the intention of the Ministry of Health or of the executive councils that there should be arbitrary decisions. When the medical profession had agreed to a general limitation of individual lists to 4,000, it was understood that at the start there

should be latitude to avoid splitting families. After discussion with the profession a circular was sent by the Ministry to executive councils last November suggesting that the lists should be examined because there were wide discrepancies. The general view of the medical profession as well as of the Ministry was that it would be impossible to get the type of service desired if these grossly overloaded lists were allowed. Before the Birmingham Executive Council was able to consider the matter the doctor to whom Mr. Lindsay had referred wrote to that council saying he found his list, which was more than 4,000 above the agreed figure, was too much for him. He asked the executive council to help in trying to reduce the list. The council was obliged to consider the appeal made by the doctor. The doctor himself was asked for his views. He felt that if he could limit his area of operation to a district outside Birmingham where he had a large practice and where there were few other doctors whom patients could choose he would be doing the right thing. He suggested those he wished to be removed from his list, and the Executive Council notified the names after they had been approved by the doctor concerned. Mr. Blenkinsop said that the Ministry could not accept the principle that those who came on the list last should be removed first. The action of Birmingham Executive Council had enabled the doctor to keep his practice over the 4,000 limit in an area with few alternative doctors and to release patients for whom there were a number of alternative doctors. The executive council had notified the surplus 3,000 patients, appending a note of the other doctors in the area whose lists were below the maximum figure. Mr. Blenkinsop felt that in this case the Ministry had looked at the problem and tried to find a solution fair both to the patients and the doctor. It was true that it was difficult to get accommodation for a married assistant, but it might be possible to get an assistant in the second practice to which Mr. Lindsay had referred. Many members of the medical profession felt that 4,000 was too high a figure, and it would be impossible to leave one doctor with over 8,000 on his list while other experienced doctors had much smaller lists. For the benefit of the patients the Ministry must in the friendliest way try to get some redistribution. He assured the House that the Ministry and the executive councils did not desire to take arbitrary action or to break up families or to take individuals off the list because it was a few over the maximum. There was no need to give fresh instructions to executive councils which had used reasonable discretion in the matter and had examined individual cases. The Ministry could examine individual cases of special hardship. He was anxious that the country should understand that there was no desire for arbitrary action and that the Ministry was anxious to secure the best personal service under the National Health Scheme.

No Household Remedies

Mr. KELLING asked on Feb. 10 whether Mr. Bevan knew that some National Health Service doctors declined to write prescriptions for laxatives, first-aid dressings, antiseptics, and other household remedies which before the Service came into existence were not normally obtained on a medical prescription.

Mr. BEVAN replied that it was the duty of a doctor under the National Health Service to prescribe any drug or prescribed appliance which he considered necessary for the treatment of a patient or for the prevention of disease. It was no part of his responsibility to prescribe drugs and household remedies for healthy persons for purposes of self-medication.

Unstaffed Beds—Replying to Mr. HASTINGS on Feb. 10, Mr. BEVAN said that the number of unstaffed hospital beds on Sept. 30, 1948, was 57,500 including 4,800 in sanatoria. He added that there were 7,000 numbers of nurses not actively employed, many of whom would be willing to serve in an emergency. Their names were on an emergency reserve list kept by the Department.

Tropical Diseases Centre—Mr. BEVAN informed Mr. IVOR THOMAS on Feb. 10 that it was proposed to develop a tropical diseases centre as a unit of the London University College Hospital group. He and the Colonial Secretary were anxious to ensure that this development should be worthy of the object in view, and should take place as far as possible in building and other difficulties permitted.

Medical Superintendents—On Feb. 10 Mr. HARDY asked why medical superintendents were not allowed to attend hospital management committees in the Manchester regional area. Mr. BEVAN replied that it was a matter for the committee concerned. He added that after all the desirability of making this arrangement.

Lifeboat—Where a lifeboat has to be used to convey a patient to hospital the expense will be met by the regional hospital board. Where a patient has to be called out to convey a doctor to a patient, the expense will be met by the local executive council.

Universities and Colleges

UNIVERSITY OF LONDON

George Lindor Brown, M.Sc., M.B., Ch.B., F.R.S., has been appointed to the Jodrell Chair of Physiology tenable at University College, from Oct. 1.

The title of Professor of Neuropathology in the University has been conferred on Alfred Meyer, M.D., in respect of the post held by him at the Institute of Psychiatry.

A name was omitted from the list of recognized teachers of the University printed in the *Journal* of Jan. 22 (p. 159). Mr. C. H. Gray has been recognized as teacher of surgery at the Royal Free Hospital School of Medicine and Dr. J. D. S. Flew as teacher of obstetrics and gynaecology at University College Hospital Medical School.

EPIDEMIOLOGICAL NOTES

Influenza

There were 64 deaths from influenza in the great towns of England and Wales in the week ended Feb. 5, as against 37 in the preceding week. This is not a high figure in comparison with the corresponding one for any previous year other than 1948. There has been an increase in the number and size of outbreaks reported from residential schools, Service establishments, and so on, but in all these outbreaks the disease appears to have been relatively mild and short-lived. Outbreaks are widely scattered.

In France the epidemic is on the wane, but in some regions a slightly higher proportion of serious cases is being reported than in the earlier stages of the epidemic. A number of comparisons between different strains have now been made and show that the virus isolated from cases in the United Kingdom in the latter half of January is identical with strains currently obtained from Continental Europe.

Discussion of Table

In England and Wales there were decreases in the notifications of scarlet fever 120, acute pneumonia 115, whooping-cough 85, and dysentery 44, and increases in the incidence of measles 1,402, cerebrospinal fever 21, and diphtheria 10.

The largest change in the local incidence of scarlet fever was a decrease of 37 in Lancashire. Notifications of whooping-cough increased in Yorkshire West Riding 57 and Lancashire 56 and decreased in Warwickshire 42.

The incidence of diphtheria increased in Lancashire 15, due to the experience of the county boroughs, and in Glamorgan-shire 7.

The largest increases in the notifications of measles were Staffordshire 215, Middlesex 190, London 130, Southampton 120, and Yorkshire North Riding 120; the only large decrease was 95 in Lancashire.

Small outbreaks of dysentery were notified during the week from Cornwall, Bodmin M.B. 7, and Dorset 6 (Beaminster R.D. 3 and Bridport R.D. 3). Other large centres of infection were Lancashire 15, London 6, and Worcestershire 6. Of the 20 cases of poliomyelitis 11 were notified in London and the south-eastern counties; the largest returns were London 4, Southampton 3, Kent 2, and Somerset 2.

In Scotland the only rise in the notifications of infectious diseases was 45 for measles; there were falls in the incidence of scarlet fever 16, diphtheria 14, and whooping-cough 11. Notifications of dysentery increased in Edinburgh from 4 to 9 and decreased in Glasgow from 21 to 7.

In Eire increases were recorded in the notifications of measles 77, scarlet fever 22, and whooping-cough 14. The largest outbreak of measles during the week was in Donegal, Stranorlar R.D. 17. The increased incidence of whooping-cough was contributed by Dublin C.B., where the notifications rose from 27 to 53.

In Northern Ireland a decrease occurred in the notifications of measles 24 and scarlet fever 25. In contrast to the trend for the whole country an increase in the notifications of measles was recorded in the counties of Down 14 and Tyrone 10.

Week Ending February 7

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,372, whooping-cough 3,168, diphtheria 116, measles 13,800, acute pneumonia 1,016, cerebrospinal fever 32, acute poliomyelitis 9, dysentery 75, paratyphoid 4, and typhoid 6.

No. 4

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Jan. 29.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths are for: (a) The 126 great towns in Engl

(b) London (administrative county) (c) The

The 13 principal towns in Eire (e) The 10

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

¶ Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

Medical News

Surgeon to the King

Professor James R. Learmonth has been appointed Surgeon to his Majesty the King. Professor Learmonth is Regius Professor of Clinical Surgery in the University of Edinburgh, and is already Surgeon to the King's Household in Scotland.

Rheumatism Congress in New York

The British Association of Physical Medicine (45, Lincoln's Inn Fields, London, W.C.2) announces that a rheumatism congress will be held in New York in June, 1949. Members wishing to have further information about this congress should communicate with Dr. O. Savage, Deputy Honorary Medical Secretary, Empire Rheumatism Council, Tavistock House North, Tavistock Square, London, W.C.1.

Old People's Welfare

The Third National Conference on "The Care of Old People" was held in London on Nov. 26-27, 1948. The proceedings of this conference have now been published in full as an attractive booklet which can be obtained, price 2s., from the National Council of Social Service, 26, Bedford Square, London, W.C.1.

Mosquito Control

There has just been published a new edition of a *Memorandum on Measures for the Control of Mosquito Nuisances in Great Britain*, which appeared originally in 1940. This has been extensively revised, particularly in regard to the use of the more modern insecticides such as D.D.T. and "gammexane." The *Memorandum* is published by the Ministry of Health (H.M.S.O., price 9d.).

Hunterian Society Dinner

The annual dinner of the Hunterian Society, held at Grosvenor House on Feb. 10, was greatly enjoyed by a distinguished company of members and guests. Sir Walter Monckton, K.C., who proposed the toast of the Society, said that though John Hunter was the father of scientific surgery he must have been the worst witness ever to have appeared in a court of law. From his experience as chairman of St. George's Sir Walter felt justified in saying that life at the hospital was quieter than in Hunter's time: to-day one was unlikely to see any of the surgeons driving from Earls Court to Hyde Park Corner with a couple of buffaloes in the car. In reply the president of the Society, Dr. Mather Cordiner, referred to the successful meetings of the previous year and expressed the hope that medicine would continue to attract adventurous spirits. The health of the Lord Mayor and the Corporation of the City of London was proposed by Dr. Franklin Bicknell, and Sir George Aylwen in reply said that he had not realized until a recent visit to Australasia what the leadership of this country meant to medicine and surgery in the Dominions. Mr. Dickson Wright proposed the health of the guests in a witty speech, in which he referred to the present as a time of "weeping, wailing, and nationalization of teeth." Sir Henry Dale in reply said that the Hunterian and kindred societies were in a central position to advance medical knowledge by observation, discussion, and communication, but it would be necessary to cling firmly to independence. Sir Ronald Burrows, K.C., who also replied for the guests, emphasized that both doctors and lawyers must be completely free to follow the course which is to the best advantage of their clients. During the course of the evening the president presented the gold medal of the Society to Dr. J. Lieber for the best essay on the treatment of obesity submitted by any general practitioner in the Empire.

Rehabilitation and Resettlement

The second report of the standing committee on the Rehabilitation and Resettlement of Disabled Persons has just been published. The report reviews the developments of the last two years in the field of rehabilitation and suggests that when the regional hospital boards have had time to review these services in England and Wales accommodation and equipment will be found to be satisfactory in most parts of the country. A brief description is given of the special centres for cardiac cases and of the experimental industrial neurosis unit at Sutton Emergency Hospital. There is also a short account of the special measures taken for the rehabilitation and resettlement of coal-miners. The report is published by the Ministry of Labour and National Service (H.M.S.O., price 9d.).

French Award

The French Government has conferred the Médaille de la Reconnaissance Française on Dr. L. G. Blair.

Honorary F.R.C.O.G.

Sir Henry Dale, O.M., F.R.S., and Professor J. Heyman, of Stockholm, have been elected to the Honorary Fellowship of the Royal College of Obstetricians and Gynaecologists.

McNeill.—On Feb. 7, 1949, at Tottenhall, Wolverhampton, Ina Lochhead

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Infective Hepatitis

Q.—In cases of infective hepatitis in children that I have seen recently there has been rapid clinical improvement without corresponding improvement in physical signs. Should one treat these cases with reference to clinical condition only, or does the presence of an enlarged liver and spleen call for additional rest in bed? Are any further investigations indicated?

A.—The liver may remain enlarged for several months after a severe attack of infective hepatitis. This does not necessarily mean that post-hepatitic cirrhosis is going to develop. If, however, the liver edge becomes irregular or the spleen enlarges, the development of cirrhosis can be expected. One of the early indications in a patient convalescing from acute infective hepatitis that the liver is on the way to becoming cirrhotic is to find that, despite an adequate intake of food, the plasma albumin is low and the plasma globulin high. In the particular case mentioned it is advised that the plasma albumin and globulin be determined, and also the cephalin cholesterol and the thymol flocculation tests performed. If none of these indicates any abnormality the child can be allowed to get up and about; it is advisable that exercise be somewhat restricted for a start. The case should be watched for any untoward symptoms until the liver has returned to normal.

Premenstrual Tension State

Q.—Is there any alternative treatment for the cerebral anaemia of the premenstrual phase, with its attendant symptoms of depression, lack of concentration, and extreme fatigability, in a patient who has failed to respond to a salt-free diet with ammonium chloride therapy, and still complains of greatly reduced capacity for mental work for at least five or six days?

A.—The origin of a premenstrual tension state can often be traced back to an emotional shock, domestic upset, or marital difficulty, especially in a highly strung young woman. It would therefore be helpful to know the age, marital status, menstrual, and marital history of the patient as well as her temperament. A mistaken conception of the purpose and function of menstruation should also be excluded. Although it was originally suggested that the condition might be due to a relative deficiency of progesterone, it has recently become more usual to ascribe the syndrome to a high production of oestrogen and progesterone or to an increased body sensitivity to these hormones. Consequently the administration of testosterone is now favoured, even by Freed (*J. Amer. med. Ass.*, 1945, 127, 377), who had earlier recommended the treatment by "decongestion" already tried by the questioner. Testosterone propionate, 20 mg. injected twice weekly throughout the cycle, is advised for severe cases, while in the milder degrees methyl testosterone, 10 mg. sublingually for ten days premenstrually, may suffice. With the higher dosage manifestations of virilism should be watched for. The symptoms of the premenstrual tension state are not generally imputed to cerebral anaemia, but in this patient examination of the blood picture to exclude anaemia would be advisable.

High-frequency Diathermy for Hypertension

Q.—Has high-frequency diathermy proved of any value in cases of essential hypertension or for pain subsequent to coronary thrombosis? If so, what is the dosage, and are there any contraindications?

A.—High-frequency diathermy has been used for over ten years in the treatment of hypertension with varying degrees of success. The fall is most pronounced after the first treatment, and gradually decreases till a more or less constant level is reached. The degree of fall varies with individual cases, being

as a rule greatest with high pressures. According to Meyer's technique, one electrode 10 to 12 cm. in diameter is applied over the region of the heart; the other is placed over the vertebral column, either at the level of the fourth dorsal vertebra or on the left side of the neck at the level of the stellate ganglion. The wavelength is 6 to 16 metres, and sessions lasting 8 to 15 minutes are given every second day. A course of treatment comprising eight to twelve sessions. The systolic blood pressure is measured every two minutes, and any sudden fall or any rise is an indication to stop treatment for that session. Subjective sensations of precordial discomfort or nausea are contraindications to further treatment. Even when the blood pressure is not materially lowered the symptoms may be greatly relieved. This treatment is also used for angina pectoris, but has proved of little value for the sequelae of coronary thrombosis.

Pilocarpine and Eserine

Q.—Can pilocarpine and eserine sometimes produce a dilatation of the pupil in the same way as does atropine? If so, how is this brought about? Is there any literature on the subject?

A.—Most substances like pilocarpine, eserine, and atropine have two actions, the one being the opposite of the other. If 1 mg. of atropine sulphate is taken by mouth, the first effect is to slow the heart rate and to make the skin moist. Then, after one hour (or less), the opposite effect is seen: the heart rate quickens and the skin becomes dry. It is therefore conceivable that pilocarpine and eserine, given in a large dose, may have the same effect as excess of acetylcholine and cause paralysis of the muscles supplied by the third nerve as atropine does, and therefore produce pupil dilatation. This is a very unlikely action, but somewhat more probable with eserine than with pilocarpine. There is no published discussion of this double effect in the eye, but Gaddum's *Pharmacology* (3rd ed., p. 185) might be consulted, and then the paper by E. Bülbring (*Brit. J. Pharmacol.*, 1946, 1, 38), which contains several examples of this double action.

Tinnitus

Q.—A patient aged 52 has been suffering from menopausal tinnitus for 14 months. The left side only is affected, and despite the administration of barbiturates, stilboestrol, and vitamin B complex, and extraction of all the teeth, the condition continues unabated. There is no impairment of hearing. The patient is showing signs of nervous exhaustion, and I should be grateful for suggestions about further lines of treatment.

A.—A trial should be made of bromides, or, if there is hypertension, of iodides. Recently Garnett Passe (*Journal*, Nov. 6, 1948, p. 812) has treated cases of Ménière's disease by sympathectomy, and has claimed relief of the tinnitus in a proportion of them. If these results are confirmed by other workers the operation might be advised in this case. It must be admitted, however, that in many cases tinnitus can only be alleviated.

Dhobie Itch

Q.—A patient has suffered from attacks of dhobie itch every few months since coming to the Tropics eighteen years ago. These cleared up after one or two applications of an ointment composed of 2% salicylic acid, 2% sulphur, and 1% ammoniated mercury in equal parts of lanoline and petroleum jelly. After a course of tablets containing vitamins and calcium pantothenate, for the last three months he has had a lowered immunity to this infection. What is the explanation of this? The infection is now controlled by daily inunction of the above ointment. Clothing is boiled. Is there any danger in the prolonged use of the ointment? If infected clothes are not boiled, how long will the fungus live in them? Has the cause of the scrotal dermatitis among prisoners of war in Japanese hands at Singapore been established yet?

A.—The diagnosis should be confirmed by direct examination and culture. If positive, infection between the toes and of toe-nails should be considered. Seborrhoeic dermatitis would seem to be a possible diagnosis, and a watery solution of one of the dyes a suitable application. The taking of vitamins

and calcium would not affect a fungous infection, but a state of health demanding such measures might bear upon the diagnosis of a seborrhoeic dermatosis. There is no danger in using the ointment mentioned apart from idiosyncrasy and sensitization. Repeated boiling or formalin treatment of clothes are effective fungicidal measures. Scrotal dermatitis may be evidence of a riboflavin deficiency. The Singapore cases are referred to by Sefton (*Brit. J. Derm. Syph.*, 1947, 59, 85-103 and 159-168).

Frequent Micturition

Q.—An unmarried female aged 26 has suffered from frequency of micturition since the age of 12. This greatly incapacitates her in her work, which entails attendance at lengthy public functions, and causes great mental strain. She can rarely hold urine for more than two hours, frequently passes it every hour, and sometimes several times in an hour, without any apparent predisposing cause. Investigation of the genito-urinary tract reveals no abnormality. The urine is acid with no abnormal constituents; no pathogenic organisms have ever been found. Treatment with alkaline mixtures has had no effect, and sedatives have proved useless. Would you advise the use of vasopressin, and, if so, in what dosage? Would there be any ill effects?

A.—It is assumed that a lesion in the nervous system has also been excluded. There is no indication for the use of vasopressin unless it is established that the frequency is due to polyuria. If there is neither nocturia nor nocturnal enuresis, then the condition is probably a functional one. If not already done, cystometric examination, including estimation of the bladder capacity, should be carried out by a urologist. Treatment would depend on the results of cystometry, but bladder drill—teaching the patient to retain increasing amounts of fluid in the bladder—is well worth trying. Among the drugs, atropine as a parasympathetic depressant, or ephedrine as a sympathetic stimulant, are most likely to be beneficial.

Vaccination for Recurrent Herpes

Q.—Can recurrent herpes simplex be treated by smallpox vaccine? What is the technique, and what are the results?

A.—Recurrent herpes has been treated, with variable success, by vaccinating patients with plasma from their own herpetic vesicles, with a formalinized 10% suspension of herpes-infected pads of guinea-pigs (*Brain, Brit. J. Derm. Syph.*, 1936, 48, 21), and with smallpox vaccine. Arnold (*Proc. Clin. Honolulu*, 1944, 10, 91) reported considerable success in the treatment of 14 patients by this last method. The technique is that normally employed in vaccination, and the procedure may be repeated at fortnightly intervals.

"Dry Socket"

Q.—What is the pathology of the dry dental socket? Can this be diagnosed before extraction, and what is the subsequent treatment?

A.—"Dry socket" is in reality a misnomer, since it is used to describe a septic socket the delay in healing of which is due to infection of the supporting bone. The condition results usually from three main causes: (1) the dislodging of the clot from the socket by mechanical means, such as misguided syringing or plugging into the socket; (2) infection in the socket causing disintegration of the blood-clot; (3) occasional failure of the blood-clot to form, due to excessive local vasoconstriction caused by large amounts of local anaesthetic. It is more prevalent in the lower jaw, owing to the fact that dependent drainage does not obtain as in the upper jaw; and any tooth showing sepsis at the apex is suspect, since any such tooth with deep infection at the bottom of the socket is liable to cause breakdown of the clot. After the tooth has been extracted the socket, if septic, should be treated as for any other septic condition—heat in the form of hot mouth-washes should be applied (hypertonic saline), and local penicillin in the form of pastilles given to reduce the infection; the pain in severe cases may be controlled by very light plugging of the socket with obtundents such as oil of cloves or "dentalone."

Hallux Valgus

Q.—A man aged 55 had a cerebral haemorrhage about six years ago, with resultant hemiplegia of the left side. He has now almost fully recovered the power and movements of the hand and leg, but has extreme hallux valgus, with the hallux at right-angles under the second and third toes. Would an operation be possible and likely to effect considerable improvement? What anaesthetic would be best? He is in good general health but has a chronic bronchial wheeze and cough.

A.—The treatment of hallux valgus should depend on the extent of the disability, as judged from the symptoms and functional capacity, rather than on the anatomical condition of the foot alone. Thus some patients, even those with severe deformity of the toe, are not sufficiently disabled to make operation worth while, whereas others, with relatively slight deformity, may demand operation for relief of arthritic or pressure symptoms. In the case under discussion there would be no particular contraindication to operation; and, if the disability is considerable, correction should be advised. Opinions differ on the question of the most suitable operation, but most would agree that a procedure of the Keller type, with excision of at least the proximal two-thirds of the proximal phalanx of the hallux, would lead to considerable improvement. Thiopentone induction, followed by nitrous oxide and oxygen or cyclopropane and oxygen, would be a suitable anaesthetic.

NOTES AND COMMENTS

"Rapid" Rat Test for Pregnancy.—Dr. A. D. TELFORD GOVAN (Glasgow) writes: In answer to a question regarding the diagnosis of pregnancy by means of rat tests ("Any Questions?" Jan. 15, p. 121) you referred specifically to a 2-hour test. There are four tests described in which the rat is the animal used. These are the 2-, 6-, 24-, and 36-hour tests respectively, all of which have had the description "rapid" applied to them. Eberson and Silverberg¹ reported their results on 24- and 36-hour rat tests and claimed a high degree of accuracy. Similar claims were made by Reiprich,² Walker and Walker,³ and Kelso.⁴ Later, in 1942, Salmon and his colleagues⁵ described a 6-hour test which was accurate in practically 100% of cases. Kupperman, Greenblatt, and Noback⁶ claimed a similar accuracy for the 2-hour test. In the research department of the Glasgow Royal Maternity and Women's Hospital we carry out approximately 1,500 pregnancy tests per year for hospitals and practitioners. During the past year we made a comparison of the 2- and 6-hour rat tests with the Friedman and Aschheim-Zondek tests. Immature female rats were used, and in our technique we doubled the usual dose and injected 1 ml. of urine intraperitoneally into either iliac region. We have found 2-hour tests quite unreliable, due to the difficulty experienced in reading the results. On the other hand, the 6-hour test was very easy to read and found to be as accurate as the Friedman and Aschheim-Zondek tests. Not only was the congestion of the ovaries more marked than in the 2-hour test, but in the majority of cases haemorrhagic follicles appeared. In our experience the 2-hour rat test, because of the difficulty in reading results and the too great importance of the personal factor involved in interpretation, is not suitable for use in the average laboratory. We would, however, recommend the 6-hour test using the double dose indicated. It is speedy, easy to perform, easy to read, and highly accurate.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY FEBRUARY 19 1949

THE SECRETARY REPORTS

WHITLEY COUNCILS

The term Whitley Council has appeared from time to time in these columns. It may be as well to indicate rather more precisely what it means in relation to the medical profession. Whitley Councils derived their name from the Rt Hon J H Whitley M.P. Chairman of a Government Committee appointed in 1916 on relations between employers and employees. Broadly, the Committee recommended the formation in well-organized industries of joint negotiating machinery, statutory regulation of wages in badly organized trades, a permanent court of arbitration and Ministerial authority to hold inquiries regarding disputes. Subsequently the Whitley idea, which gained a firm footing in industry, was extended to non-industrial fields including the Civil Service and the Local Government Service.

In pre-Act days questions of remuneration for insurance practitioners were negotiated directly between the Ministry of Health and the Insurance Acts Committee, there being no permanent conciliation machinery in existence. Arbitration on major points of difference was sought as a last resort. It is hardly an exaggeration to say that the first 30 years of National Health Insurance were punctuated by a series of crises on questions of remuneration. A permanent negotiating machinery backed by arbitration is likely to secure better relations and better results.

Government's Proposals

The Government's first proposals for the establishment of Whitley machinery for persons employed in the National Health Service contemplated a National or General Council and a series of Functional Councils, each of these bodies consisting of representatives of employers and representatives of those employed in the Service. The Functional Councils would be competent within their own sphere to decide questions which affect only that sphere, including questions of remuneration. The General Council would secure co-ordination between the various Functional Councils and deal with matters which concern more than one Functional Council. At the regional level it was proposed that there should be Regional Hospital Board Whitley Councils consisting on the employer's side of representatives of the regional board and on the staff side of representatives of the organizations represented on the Functional Councils. The third tier in the proposed structure is found at the hospital level, the regional boards being asked to encourage the setting up of staff committees in each hospital.

It was not clear that the Medical Functional Council would have complete autonomy in determining conditions of service and remuneration of members of the profession engaged in the new Service. It appeared that in certain circumstances decisions affecting the profession might be taken by a body composed predominantly of persons who were not members of the profession. The Association, in common with other interested organizations made representations to the Ministry on these early proposals and after considering the views of the various bodies the Ministry issued revised proposals in March, 1948. Later that year the Ministry summarized its proposals for the application of Whitley machinery in the case of the medical profession as follows:

The Medical Whitley Council—There would be a Medical Council on a functional basis, which would be responsible for dealing with all matters which concern the medical profession only, such as the remuneration and other conditions of service of doctors participating in the National Health Service. The decisions of the Functional Council on these matters would not need confirmation or ratification by any other Council.

It would probably be convenient for this Council to set up sub-committees to deal with different branches of the profession—e.g., hospital and specialists' services, general practitioner services, public health service. The relations between the Council and the sub-committees would be matters for determination by agreement between

the parties concerned, but our idea would be that the conclusions of the subcommittees would be subject to confirmation by the Medical Whitley Council. They would not require confirmation by the General or any other Council.

The Medical Whitley Council would consist of two sides, the management and staff sides. The management side would contain representatives of the regional hospital boards and boards of governors of teaching hospitals as the employing bodies, the Ministry of Health and Department of Health for Scotland, and also of the local authorities as employers in the public health service. The composition of the subcommittee would vary with the services concerned. The composition of the staff representing the medical profession would be a matter for representatives of the profession to decide for themselves.

The General Council—There would be a General Council made up of representatives of the several Functional Councils. The General Council would be responsible for matters which are of common concern to more than one profession or grade or staff in the National Health Service—e.g., arbitration machinery.

There is also a proposal for a Scottish Council to deal with matters which might require to be considered in the light of special Scottish conditions.

It was emphasized to the Ministry that the profession was anxious that the machinery dealing with general practitioner and public health remuneration should be established as soon as possible. At the same time the Ministry was informed that the general plan set out above was regarded as acceptable on the understanding that all matters of terms and conditions of service of doctors participating in the National Health Service—other than those which it may be agreed to be matters for direct agreement between the Minister and the profession—fall to be decided by the Functional Council without the need of confirmation or ratification by any other body. The Ministry was asked for its suggestions as to the numerical size of the general practice and public health subcommittees. Up to the present, however, it has been unable to proceed with the establishment of a Medical Functional Council because the local authority associations (who will be represented on the management side to the extent that they are employers of practitioners in the public health service) have raised certain difficulties to which attention has already been drawn in these columns.

Present Position

The present position is that a General Council has been set up and is now dealing with matters of common interest such as arbitration procedure and the constitution of joint consultative councils in individual hospitals. The management side of the General Council includes representatives of the Ministry of Health, the Department of Health for Scotland, regional hospital boards, boards of governors, the Association of Executive Councils, and the local authority associations. The staff side consists of representatives of the staff sides of the various Functional Councils which have been established—e.g., the Nursing and Midwives Council, the Pharmaceutical Council, etc.

Seven Functional Councils have been set up for dealing with questions of remuneration and other conditions of service for each of the following classes—namely, Pharmaceutical, Optical, Nurses and Midwives, Professional and Technical Grades (two Councils (a) and (b)), Ancillary Grades and Administrative and Clerical Staffs. The management side of each of these Functional Councils includes representatives of the Ministry and Department of Health for Scotland, regional hospital boards and boards of governors, the local authority associations (except in the case of the Administrative and Clerical Staffs Council) and in the case of the Administrative and Clerical Staffs Council representatives of the Association of Executive Councils. The staff sides consist of representatives of the professional or other organizations concerned.

National Health Service

PRIVATE AND PUBLIC PATIENTS REFERRED TO PATHOLOGISTS OR RADIOLOGISTS

It is recognized that a person may elect to receive some of the benefits of the National Health Service and not others—e.g., that a person who is the private patient of a general practitioner may elect to receive specialist treatment as a public patient. The position has not been so clear, however, where a consultant wishes to have the opinion of a pathologist or radiologist on a private patient and the latter desires the services to be obtained under the public service.

The Ministry of Health makes the following statement:

1. A private patient seen at the physician's or surgeon's consulting-room may be:

(a) Referred to the pathologist or radiologist at the hospital through the out-patient department for examination free of charge as an ordinary National Health Service out-patient.

(b) Referred to a specialist, pathologist, or radiologist as the latter's private out-patient, if the pathologist or radiologist is allowed by his conditions of service to have private practice. In this case the hospital charges fees under the First Schedule of the Pay-bed Regulations and the pathologist or radiologist may charge the patient fees within the maxima in the Second Schedule.

2. Where the private patient of a physician or surgeon is in Section 5 accommodation as an in-patient:

(a) The physician or surgeon may, with the patient's consent, refer him to a pathologist or radiologist on the staff of a hospital for examination and report, the patient being regarded as the private patient of the pathologist or radiologist (this is, of course, if the pathologist or radiologist is permitted by his conditions of service to have private practice). In this case the hospital charges under the First Schedule of the Pay-bed Regulations are not made, but the pathologist or radiologist may charge the patient fees for his professional services within the maxima laid down in the Second Schedule.

(b) The physician or surgeon may, subject to what is said below, obtain an examination and report by a pathologist or radiologist in exactly the same way as if the patient occupied a general ward bed, free of extra charge. The contract of a whole-time pathologist or radiologist who was not allowed private practice should provide specifically that he could render service to patients in Section 5 accommodation. A part-time pathologist or radiologist could, of course, contract with the board to provide service for patients in Section 5 accommodation without charging the patient a private fee; but if his contract with the board did not provide for such service he would be under no obligation to agree to do the examination and report as part of his service for them, and could insist on an arrangement under 2 (a).

In cases 1 (b) and 2 (a) it would be open to the Hospital Management Committee or Board of Governors to waive the maximum professional fees in an appropriate number of cases where the patient agreed to pay more than the maxima.

HOSPITAL PROVISIONAL CONTRACTS

The Minister of Health has requested regional hospital boards and boards of governors to notify hospital medical staff whose provisional contracts expire on March 31 that they propose to extend the provisional contracts until July 4.

Meanwhile the consultants and specialists are negotiating their terms and conditions of service with the Ministry, and regional hospital boards and boards of governors are reviewing hospital posts and staff before readjusting duties where necessary.

CENTRAL CONSULTANTS AND SPECIALISTS COMMITTEE (SCOTLAND)

The Central Consultants and Specialists Committee (Scotland), at a meeting in Edinburgh on Feb. 4, accepted a proposal put forward by the Royal Scottish Medical Corporations for the setting up in Scotland of a Joint Committee similar to the Joint Committee established for the United Kingdom to negotiate with the Government on matters affecting consultants and

specialists in the National Health Service. The committee would consist of the four Scottish representatives on the central Joint Committee, and in addition one representative each of the Royal Scottish Corporations and of the Scottish Committee of the R.C.O.G., and three representatives of the Central Consultants and Specialists Committee (Scotland), a total of 11 members.

In moving acceptance of the proposals, Dr. W. D. D. Small, P.R.C.P.Ed., explained that on the central committee it was accepted that there would be need for a "top-level" committee of this kind to discuss with the Secretary of State for Scotland, as the Minister responsible to Parliament, and his officers, as the administrators of the Health Service in Scotland, matters affecting Scottish consultants and specialists. Mr. T. Murray Newton, referring to what he described as a lively and critical meeting of the Western Regional Consultants and Specialists Committee, over which he presided, said he was instructed to ask for greater representation of the Consultants and Specialists Committee (Scotland) to meet the needs of the Western Region, which embraced the largest group of consultants. Dr. Small, claiming that the basis suggested was equitable, adhered to his motion, since he felt that to do otherwise would mean reference back and harmful delay.

Dr. E. R. C. Walker, Scottish Secretary, suggested that it might help unity and urgency if the constitution was meantime considered to be provisional. Mr. Murray Newton said that in view of the discussion he would accept the responsibility, on behalf of the Western Regional Committee, of agreeing to the proposal on this basis. It was agreed that the provisional period should be one year.

The committee also considered a minute of a meeting of representatives of the Scottish Negotiating Committee and the Medical Superintendents' Society with the Department of Health for Scotland, at which the fear was expressed that a memorandum on hospital administration issued by the Department of Health to regional hospital boards was being regarded by certain boards of management as a directive, and that the duality of control which would result from the introduction of a lay administrator in addition to a medical superintendent would lead to disharmony in the administration of hospitals and would reduce the status and prestige of the medical superintendent, traditionally recognized as the chief executive in Scottish hospitals. Sir George Henderson, on behalf of the Department, gave the deputation an assurance that the memorandum was advisory in nature and suggested that the experiment should be allowed to continue for six months, after which there could be a further meeting with representatives of the profession to review the situation. It was agreed that these developments were of particular importance since they might ultimately lead to the abandonment of the hitherto accepted system of the great teaching hospitals of Scotland.

The matter was remitted to a subcommittee, but meantime it was suggested that acceptance of appointments as superintendents of grouped hospitals was inadvisable until more was known of the salaries likely to be attached to these posts.

FACULTY OF OPHTHALMOLOGISTS

The Honorary Secretary reports that at the Council meeting held on Dec. 17, 1948, it was revealed that the memorandum H.M.C. (46) 83 on the development of the hospital eye service had been prepared by the Ministry under the mistaken impression that it incorporated the views of the Faculty. This document is being revised and rewritten. It was stated that the Committee of Management of the Examining Board in England had accepted the recommendations of the Council regarding diplomas in ophthalmology; these recommendations will appear in the Annual Report of the Faculty.

As a result of the ballot among members of the Council, the following have been elected the representatives of the Faculty on the Ophthalmic Group Committee of the British Medical Association: Mr. George W. Black, the Hon. G. J. O. Bridgeman, Mr. J. D. M. Cardell, Mr. J. H. Doggart, Mr. O. M. Duthie, Mr. A. B. Nutt.

Alert... AND FREE FROM PAIN

When the burden of pain proves too heavy, mental outlook becomes distorted. In such a case the drug of choice is 'Physeptone' which gives satisfactory analgesia while leaving the mind clear.

To Maintain proper Nutrition During and After Pregnancy

THE results of modern anaesthetics have emphasized the importance of proper nutrition of the expectant mother, in securing a normal pregnancy, labour and puerperium and in endowing the infant with an ideally sound constitution.

The use of 'Ovaltine' throughout pregnancy goes far towards ensuring this ideal state of nutrition. 'Ovaltine' is a natural food tonic prepared from milk, egg extract, cocoa and soya. 'Ovaltine' is delightful in taste and is so readily digestible that restricted diets does not preclude its use.

During lactation its use enriches the milk and permits the mother to continue adequate feeding until the normal time for weaning occurs.

Fasciomyositis, Postural- relieved by a SPENCER Support

The patient pictured here, age 41, was presented to the Orthopaedist in May 1947 with long standing complaints of "Rheumatic" pain, especially in the back. The pain was frequently disabling.

The condition was diagnosed as fasciomyositis, postural—and initial treatment included the wearing of a plaster cast for 10 weeks; then a leather and steel jacket for 3 months. The patient complained of their heaviness and discomfort. A Spencer Support was applied in December 1947. Results have been excellent. The patient has found the Spencer Spinal Support very comfortable. It has corrected the lordotic condition, and improved the posture.

Therapeutically, Spencer provides the degree of support and postural correction required; yet its light weight, ease of adjustment, and comfort help to relieve back pain and, concomitantly, to improve the patient's mental outlook.

GENERAL MEDICAL SERVICES COMMITTEE

THE N.H.S. CAPITATION FEE

A special meeting of the General Medical Services Committee was held on Feb 9, Dr S Wand presiding, to discuss a report presented by its Remuneration Subcommittee which it was proposed should form the basis of the general practitioner case for remuneration under the National Health Service to be presented to the Government as a matter of urgency. The agreed form of the report is published below.

The chairman explained that the task before the subcommittee had been to work out a method of remunerating practitioners on a capitation basis so as to implement fully the Spens ranges of income. It was the lower and middle ranges of income which formed the principal problem. The matter had been approached from the standpoint of the global sum—i.e., the total sum of money which should be made available on the basis of Spens to general practitioners as a whole. The aggregates so far achieved related to the pre-war total general practitioner income—the Spens adjustment for the amount by which that income was less than it should have been, and the addition for increase of population—had been agreed. A point which had not been settled, since exact figures were not available concerned the addition to be made for the increase in the number of principals. The pool was designed for 17,900. The number of general practitioners in the Service, as now ascertained from official sources, was approximately 20,500. Some correction would have to be made for the inclusion of assistants but probably the number of principals was not less than 20,000. There remained the question of the betterment factor. The Government at the end of 1946 laid down an addition of 20% to net income (or a compound figure of 34% to gross) though at that time the increase for middle class budgets over the pre-war figure was between 45 and 50%. The expert's figure for 1948 was 85%, so that it was evident that the Government addition was now quite inadequate and unless the betterment factor was properly adjusted the remuneration battle would not be won.

Dr F Gray pointed out the desirability of representing to the Ministry that the financial inducements for entrance into general practice should compare reasonably with the inducements to enter special practice. There was a strong financial bias in favour of specialism and unless there was a substantial improvement in the financial expectations of the general practitioner there was a danger that an unduly large number of able men would seek to become specialists. It was agreed to incorporate this point in the memorandum.

The Betterment Factor

A long discussion then took place on the question of the appropriate betterment factor in relation to the increase in middle class budgets. There was some difference of opinion on whether an exact figure or a range between two figures should be proposed to the Government, and there was dissent from any proposal that practitioners' remuneration should be automatically tied to cost of living. The chairman said that the important thing was that the negotiators should go to the Ministry with a figure which could be substantiated.

Eventually the committee agreed that, on the most modest view, it was obvious that unless a compound figure in the region of 70% was applied to gross remuneration the available pool of remuneration would remain inadequate. This was the unanimous view of the committee.

Proposed Augmentation for First 1,000

The committee then devoted itself to considering the distribution of the pool. It was proposed in the memorandum that the additional money made available by the application of a proper betterment factor and other adjustments should be devoted entirely to the augmentation of the capitation fee for the first 1,000 on all practitioners' lists. Thereby all practitioners would benefit, but those with the smaller lists would benefit to a relatively greater extent.

Dr H H D Sutherland pointed out that it was not only practitioners with average or below-average lists who were suffering hardship but often also practitioners with lists above the average. Formerly these practitioners managed comfortably by reason of the fact that they financed their national health

insurance practice from their private practice, and now they had twice as many 'State' patients as before, but, with the disappearance of private practice, less remuneration. It was pointed out, however, that these practitioners, like all others would benefit by what was now proposed.

It was also suggested that if a practitioner with a small list had other sources of income besides National Health Service practice he would be favoured as against his colleagues because he would have the first 1,000 on his list at a relatively high rate. An alternative proposed by one member was the closing of certain over-doctored areas and the establishment of a fund on the lines of the Special Inducement Fund to make it possible for doctors already in the area to be adequately remunerated, but this found no support.

Other objections were that the most successful doctors would be, relatively, penalized and that it would interfere with free choice if there were two classes of N.H.S. patients each with a different rate of payment. It was also urged that, if a differentiation was made, the gap between the two rates should not be large.

It was pointed out that it was desirable that the basic salary and the Special Inducement Fund should tend to disappear, the one because it was not liked and the other because it was not used. The wise course would be effectively to reduce the number of people who could plead justification for basic salary, and whatever might be the demerits of the system now proposed it had the merit of reducing the field for the two funds.

The chairman said that it was important to emphasize to the profession that this system of augmentation for the first 1,000 meant a substantial increase in the capitation fee for all practitioners. Figures were presented to the committee showing the effect on practitioners' incomes of this adjustment at varying rates for the first 1,000.

The committee agreed that any increase obtained in the global sum should be devoted to an augmentation on these lines and on the proposition of Dr Prindham it was agreed with two dissentients, that the special augmentation of the rate for the first 1,000 or the 'two tier system' be approved in principle, subject to review in the light of experience. A proposal to attach the augmentation not to the first 1,000 but to the first 1,500 or even 2,000 patients was not accepted.

The question of the additional burden of work was postponed to be taken up with the Ministry when fuller information was available, and it was then agreed that, subject to the amendments made the memorandum should be taken as the basis of the general practitioner case to be laid before the forthcoming Special Conference, which would be asked to instruct the committee to press the Government as a matter of urgency to adjust general practitioner remuneration on these lines, the adjustment being retrospective to July 5.

REPORT BY THE GENERAL MEDICAL SERVICES COMMITTEE ON THE REMUNERATION OF GENERAL PRACTITIONERS

PART I

The Adequacy of the Central Pool

1. There is now abundant evidence of the unsatisfactory character of the remuneration paid to general practitioners under the National Health Service Acts. In terms of effective purchasing power the income of general practitioners generally is down, an inevitable result of the application of an inadequate betterment factor. Many practitioners notably those with lists of average and less than average size are experiencing loss of income on such a scale as to spell hardship for themselves and their dependants. The increase of the Mileage Fund to £2 million though welcome is but a partial solution of part of the difficulty. The problems are, first, how best to secure that a sufficient sum of money is available for the remuneration of general practitioners as a whole, and secondly, to evolve an equitable method of distribution.

The Spens Recommendations

2. The recommendations of the Spens Committee accepted by the Government and the profession, provide the basis. They fall into two quite distinct parts. In the first place the Spens Committee, informed of the amount and spread of pre-war

general practitioner income, found that the total sum received was insufficient by some £3 million. It proceeded to recommend that to the gross aggregate pool, augmented by some £3 million, there should be applied a betterment factor to adjust pre-war moneys to present conditions, regard being had to two factors—to estimates of the changes in the value of money and to the increases which have taken place since 1939 in incomes in other professions. The committee goes on to say that "it is only if corresponding changes are made in the incomes of general practitioners that the recruitment and status of their profession will be maintained as against these professions."

3. The second part of these recommendations relates to a recommended spread of income in the profession with special reference to the 40-50 age group. The application of this second group of recommendations, necessarily couched in mathematical terms, is a problem of immense difficulty, and it is doubtful whether any system of remuneration can be guaranteed to secure with precise accuracy the exact percentage regarded as appropriate by the Spens Committee. But no such difficulties confront us in the calculation, on the basis of Spens, of the total sum of money which should be made available to general practitioners as a whole. Indeed, unless the aggregate sum is sufficient the recommendations for its spread among the profession can never even approach fulfilment.

How the Present Pool is Calculated

4. It follows that the first task before those who would seek faithfully to implement the Spens recommendations is to calculate the size of the total pool. The Ministry employed this approach when it first put forward its financial proposals. The Department started from the estimated pre-war total of gross incomes from all forms of general practice as calculated by Professor Bradford Hill at £28.14 million. This is an agreed figure. There was then calculated the amount, as agreed between the Government actuary and our own, by which pre-war general practitioner income was less than it should have been. The agreed figure was £3.1 million. So it was agreed between the parties that the pre-war gross aggregate general practitioner income should have been £31.24 million. The Ministry then proceeded to add to that part of the income which goes in practice expenses a betterment factor of 55%. It added to that part of the remuneration which is net a betterment factor of 20%. Compounding these two figures in terms of the betterment factor to be applied to the gross remuneration, the figure came to 34%. The Department then proceeded to add 3% in respect of the increase of the population since 1939, arriving at a gross income of £42.7 million. It was agreed between the Department and ourselves, though it could be no more than a guess, that 95% of the population would use the Service and that therefore general practitioners should get 95% of £42.7 million, or £40.5 million, in respect of service to those persons taking part in the scheme.

5. A certain sum of money, then £1.3 million, was set aside in a separate fund for mileage (recently £200,000 of the Inducement Fund and £500,000 of new money have been added to the Mileage Fund to bring it to £2 million).

6. The Department then proceeded to add certain sums for special purposes. They were 1% for inducement payments (£0.4 million), maternity fees, and grants for training assistants. Altogether the Ministry estimated that there would be an income of about £45 million from the new Health Service alone. It also drew attention to certain indirect benefits equivalent to income such as the Government's superannuation contribution of 8% of the net remuneration—estimated at about £2 million a year.

7. A scrutiny of the Ministry's main calculation reveals that many of the figures employed are agreed between the parties. For example, we agreed to accept £28.14 million as the total pre-war gross income; we agreed that £3.1 million represents the pre-war deficiency; we accepted an appropriate adjustment for the increase in population.

An Important Underestimate

8. In one important respect the Ministry's estimate of the Central Pool has turned out to be inaccurate. The £28.14 million, the estimate of gross aggregate pre-war general practitioner income, was based on a total number of practi-

tioners then in general practice as principals—viz., 17,900. It now emerges from official statements that the number of practitioners who joined the Service on the appointed day was rather more than 20,050, taking England, Wales, and Scotland together. The number to-day is rather more than 20,500. This figure includes some assistants who are on the list. Even so, a modest estimate of the number of practitioners participating as principals in the pool now available is not less than 20,000. This means that approximately 20,000 practitioners are participating in a pool that was designed for 17,900. In the original calculation the Ministry used what then appeared to be a fair figure, but subsequent events have proved it to be a gross underestimate. The profession is entitled to an adjustment of the pool in respect of the factor of the increased number of practitioners in the Service as principals, the adjustment to be retrospective to the appointed day. The amount of money to be added in respect of additional practitioners, calculated on the assumption of 20,000 practitioners, is £3½ million.

The Betterment Factor

9. The figure which was imposed by the Government, but not agreed, is the figure of 20% added to the net remuneration for what has become known as betterment. To the extent to which the betterment figure is inadequate, the whole pool is inadequate, regardless of the mode of its distribution. It is recognized that two factors are involved—the changed value of money and the increase in the remuneration of other professions—though it is clear that in introducing the second factor the Spens Committee had in mind any increase in the remuneration of other professions which would tend to make general practice relatively less attractive.

10. What is the fair betterment figure, taking into account both factors? When the Government laid down its figure of 20% at the end of 1946 the real figure of the increase for middle-class budgets was between 45 and 50%. In other words, when the Government laid down a figure of 120 in relation to 100 pre-war, the real figure was 145. The expert's figure for 1948 is 185. The profession could with reason claim that 185 should be substituted for 120. To put it at its lowest, if 120 were the right figure when the Government first put it forward, the real figure being 145, the figure now necessary to ensure that there is no reduction in real remuneration—now that the real figure is 185—is 160. Such an adjustment would only secure that the remuneration of general practitioners is not less in terms of real money than when the Government first offered the inadequate figure of 120. To put matters right, in relation to cost of living, the figure of 120 should now be replaced by something between 160 and 185. No precise figures are available on the increase in practice expenses in the last two years, though it is probable that they have gone up. Taking the most modest view, it is clear that unless a compound betterment figure in the region of 170 is applied the available pool of remuneration will remain inadequate.

11. The effect of increasing the betterment factor from 34%, the figure now being applied, to the modest figure of 70% here suggested would be of itself to increase the pool by more than £16½ million. It is not surprising that present remuneration should have been found so inadequate when it is realized by how much money the pool is short on any reasonable estimate of the changed value of money. The essence of the case is that the first task of the profession is to secure an adequate pool before the problem of distribution is approached.

The Revised Pool

12. There are set out below in abbreviated form the two calculations. The first, the Ministry calculation made before the Service started; the second, the adjusted calculation to meet the present conditions. It would be necessary from time to time to review the pool in proportion to the number of practitioners in the Service.

13. So far no reference has been made to an important factor. The Spens Committee stated "that unless the financial expectations in general practice are substantially improved the great majority of abler men will seek to become specialists." Later it is stated in the Report that "it is important to improve prospects in general practice in order to render this branch of medicine sufficiently attractive to prevent all the abler men endeavouring to enter specialist practice."

14 A crucial question is the margin between incomes in general practice and those in specialist practice in the future. The Spens Committee recommended that in the consideration

	Original Ministry Calculation	Adjusted Calculation to Meet 1949 Conditions
Pre-war total G.P. income	28	28
Spens adjustment	3	3
3% population increase	31	31
	1	1
Addition for increase in number of principals	32	32
		32
34% betterment	10½	70% betterment 25
	42½	60½
Adjust for 95% of population	40½	57½
Less mileage	1½	2
	39½	
Increase necessary	16½	
	£55½ m	£55½ m

of betterment regard should be had to the increases in remuneration of other professions. This must be held to relate not only to increases in income in other professions but to increases in other branches of the profession if the desires of the Spens Committee are to be observed.

PART II

Distribution of the Revised Pool

15 The size of the Central Pool now dealt with, we pass to the problem of its distribution or spread. Any calculations which are now possible to ascertain whether Spens is being applied to current incomes are vitiated by the assumption of the sufficiency of a betterment factor of 20% to the net remuneration or 34% to the gross remuneration. From the survey which has been completed this fact emerges. Despite this limitation, it does stand out most clearly that it is the practitioners with average and less than average lists who are suffering the greatest hardship. It is recognized that in a few instances the small list is due to deliberate restriction or to relative failure. But by and large the difficulty arises because in the absence of private practice—and it has virtually disappeared—few practitioners with average or less than average lists can secure an income of sufficient size. Inevitably the proportion which expenses bear to gross remuneration is higher for practitioners with small lists than for those with large lists.

16 Such conclusions lead the committee to the conclusion that the additional money made available in the Central Pool by the application of a proper betterment factor and the adjustment in relation to the increased number of practitioners should be devoted entirely to an augmentation of the capitation fee for the first thousand on practitioners' lists. The effect of this will be to increase the remuneration of all practitioners while increasing the rate of remuneration of practitioners with smaller lists to a relatively higher extent.

17 The committee recognizes that a case might be made out in favour of deducting from the revised pool some moneys previously regarded as additions to the pool—e.g., the Government's contribution to superannuation and the Special Inducement Fund. Even if such adjustments were made, the additional sum to which the profession is entitled, bearing in mind the Spens Committee's conclusions on the margin between general practitioner and specialist remuneration, is not less than £16½ million.

18 The effect of distributing £16½ million among the general practitioners in the Service, wholly in respect of the first thousand patients on the individual practitioner's list, would be to raise the average remuneration for the first 1,000 on every doctor's list to over 35s per head. For lists of over 1,000, the average remuneration per head for all patients on the list would vary from 26s 7d for 2,000 patients to 22s for 4,000 patients.

The Burden of Work

19 It will be noted that in this memorandum no reference is made to the greatly increased burden of work which the profession is experiencing as the result of the introduction of the Act. It could have been fairly argued that in devising its recommendations the Spens Committee based them on the assumption that the doctor would do a reasonable day's work and be left with sufficient leisure. It is difficult, as yet, accurately to express this increased burden in terms of statistics. This being so, the memorandum has been limited to considerations which are capable of statistical expression and permit of immediate action. The subject of the burden of work, including non-medical work, may be taken up with the Ministry when fuller information is available.

20 It is proposed that the system of distribution outlined in this memorandum should be reviewed when sufficient experience of its working has been gained.

Recommendation

RECOMMENDATION. That the foregoing memorandum be approved as the basis of the general practitioner case the General Medical Services Committee being instructed to press the Government as a matter of urgency to adjust general practitioner remuneration on the basis of the memorandum the adjustment being retrospective to July 5.

THE G.P. IN THE SERVICE

DR. DAIN ON COMING DISCUSSIONS

A meeting of the Tunbridge Wells Division on Feb 13 was addressed by Dr H G Dain, Chairman of Council. Invitations had been extended to members in seven neighbouring Divisions, and a large proportion of the 200 or 300 practitioners present were visitors. The chair was taken by Dr A M Pollock, chairman of the Division, who was supported by Dr J G Thwaites and Dr R P Liston, members of the Central Council and Dr Moore Ede, divisional secretary.

Dr Dain began by remarking that someone had said to him that Headquarters must now be having an easier time. But things had not worked out like that, although the problems were different. There was more to do now that the Service had been started than there was when it remained in the offing. Before July 5, in contemplation of a service which was to include the entire population, they were right in fixing their attention on the principles on which the Service should be based, and there was some disposition to-day, in considering the hardships which the Service had brought to their brethren in certain types of practice, to forget that certain principles of freedom had been maintained.

Freedom of choice would have been completely destroyed had they accepted a State salaried service, and was it supposed that under such a service certain of the letters which now appeared in the *Supplement* could have been written or published? "We have also established—though it is not as firmly fixed as it should be—the right of the practitioner to put up his plate wherever he wishes to practise, always provided that the area is not one of the few scheduled as restricted."

The Remuneration Problem

Now that the Service had started they were finding where the shoe pinched and what required modification or alteration in an amending Act or in regulations and there was the reconsideration necessary on the subject of remuneration. "Principles without pay would be a poor type of victor." In some quarters there was a demand that the B.M.A. should go to the Government and say, "Thirty shillings or nothing!" It was easy to say that, not so easy to implement it straight away. Obviously unless 100% of doctors or thereabouts were prepared to take that view and follow it up with necessary action it would be foolish to go to the Government and demand it.

What, then, was the central organization doing? The General Medical Services Committee had been investigating all aspects of remuneration in order that claims might be put forward which could not be gainsaid. The first claim was made on behalf of a group of practitioners who were believed to be suffering worst of all. The Ministry was told that something must be done urgently for rural practitioners, and the result

was the increase of the Mileage Fund by another £700,000, so that now it stood at £2 million, approximately three times what it was before July 5. It was understood from typical rural practitioners that this had gone a long way to solve their difficulties.

From the Spens Report the global sum which should represent the general practitioners' pool had been worked out. It had been possible to tender evidence to the Spens Committee by a statistical authority that the income of general practitioners in 1938 was £28 million. The Spens Committee accepted that evidence, and found that general practitioners were then being insufficiently paid. A sum of £3 million must be added to make good that insufficiency on the 1938 figures. A number of other factors had now to be taken into consideration. One was the increase in population in the course of ten years, estimated as equivalent in terms of the pool to another £1 million. Another factor was the difference in the number of principals—just over 20,000—now in the Service as compared with the original estimate of 17,900 on which the early figures were based. The same ratio would add £3½ million on this account.

The Betterment Factor

Dr. Dain then turned to the vexed question of the betterment factor. When the old capitation fee under N.H.I. was raised to 15s. 6d. in 1946 evidence from an expert economist was produced to show that cost of living had then risen from 100 before the war to 145. The Ministry agreed to an allowance for betterment of 55% on practice expenses and 20% on income less such expenses, the figure being compounded at 34% for gross income. If this betterment figure were taken, it appeared from the figures for certain representative sample areas that the Spens recommendations were being implemented, at least in the upper and middle ranges. But the same expert now produced figures for 1948 which had surprised him, although, like everybody else, he knew that cost of living had advanced since 1946. Actually the increase had been by 10 points or more each year, and at the end of 1948 the relevant figure was not 145 but 185 or more. Representations were being made at once to the Ministry that the pool should be augmented in view of the necessity shown for an increase in the betterment factor.

If substantial agreement were obtained on the subject of betterment a great deal of the difficulty concerning remuneration would be solved and Spens would be implemented in terms of present-day values. "This is the first time we shall have had the opportunity of looking at this problem squarely. We shall be in a position to say that we are not prepared to go on working in the Service and see our standard of living seriously depreciated as compared with the rest of the population." (Applause.)

At an earlier visit to the Ministry the officials had produced the White Paper of some twelve months ago on the stabilization of cost of living and income, urging that nobody should apply for increased remuneration and that when the cost of living would not go up. But the cost of living had gone up, and so far as he knew many types of worker had applied to have that increased cost of living reflected in higher rates of "wages" but only for the necessary adjustment in view of the increased cost of living. There was nothing unreasonable or out of place in this; it was happening in every

Capitation Fee and Size of Lists

The second part of the remuneration problem was to see that practitioners who because of the nature of the district in which they worked could not have large lists should not suffer. This problem was now being regarded in a comparatively new light. They had always said that whatever it happened a uniform capitation fee must be paid. The fee should be the same whether a doctor had four patients or 4,000. A standard capitation fee seemed to work reasonably well when only 10% of the population were included in National Health Insurance, but when the population were brought in it did not work so well. The proposal which would be placed before the for the first time was that for the first 1,000 on every doctor's list an increased sum should be paid, the money to come out of the increase of the pool on the lines he had just set out. This increase would apply, of course, to all principals and

partners in a firm whatever the size of their lists. It would benefit the man who had 4,000 on his list as well as the man who had under 1,000. The actual rate for the first 1,000 and the lower rate for those above 1,000 must depend on the size of the pool to be agreed and particularly on the betterment factor. On how far the suggestion of the augmented capitation fee for the first 1,000 would meet the case of practitioners in towns, in the country, and in seaside resorts he had as yet no evidence. If it did not meet the situation other methods must be thought out. The important thing was to ensure that the people working in different types of practices did not suffer materially from the change-over to a national health service. By this he did not mean that there should be no redistribution of doctors. It was evident that in some areas there were more doctors than were necessary and in others fewer. But he recalled that in his own city of Birmingham after the coming into force of National Health Insurance the distribution gradually arranged itself, the doctors going where there was a living to be made, and he hoped that any necessary rearrangement under the National Health Service would come about in the same way. They had successfully resisted any direction imposed upon them from without.

The Amending Bill

There would be an amending Bill, but it had been subject to delays, in the first place because lawyers who were considering the alterations in the Act necessary to deal with the partnership difficulty were long in reporting. They had now reported, and the Government was considering what amendment should be made. Then the Minister had promised that he would put into the amending Bill a statement that the Service would never be made into a whole-time State-salaried service by regulation. Again, the Act did not at present provide—although the Minister had given an undertaking to that effect—that a practitioner was at liberty to settle in the place of his choice, unless it was a restricted area. That was in fact now the case, but it was not yet explicit in the statute. He deplored the action of the doctors in some areas in saying, "We have got quite enough doctors here. We want our area declared over-doctored." If they all did that it would be the worst example of trade unionism—the closed shop.

The profession also desired that the amending Bill should deal with the question of foreign visitors who obtained certain benefits from the Act during their stay. He had been told in Bristol of the case of a foreign seaman who touched at several British ports, and at each of them had his eyes tested and fitted with glasses, no doubt disposing profitably of the surplus glasses on arriving home.

Another thing which it was desired to obtain was security of tenure for the specialist in his hospital appointment. It was also desired to establish fully the position of hospital medical committees in the appointment of representatives to the management committee. There was no provision for this under the existing Act so far as regional hospitals were concerned.

Then it should be made legal for the private patient to obtain his medicines and dressings within the Service. (Applause.) The only thing to be done was to seek an amendment of the Act.

From what he had said it would be evident that the central organization had not been slow in bringing matters to an issue. Action had been taken as rapidly as it was possible to get the facts together. One question postponed for the moment was that of the overwork of practitioners. Practitioners were doing a lot more work for the same money, and in this respect Spens was not completely implemented because the income ranges it laid down were on the assumption that the practitioner would do only a reasonable day's work, and would have time for recreation and study. A reasonable day's work in medical practice was difficult to assess. A doctor's work varied from day to day, and especially from season to season. The time had been too short to enable the Association to obtain such facts as would enable it to deal properly with the overwork problem, but the question would be tackled in due course.

B.M.A. Organization

Finally Dr. Dain discussed the constitution of the Association. Under the terms of the Memorandum the Association suffered from certain disabilities when it came to collective bargaining. The Association was a limited liability company not run for

profit licensed by the Board of Trade to omit the word 'limited' from its title. It could not distribute any of its moneys to its members and therefore it could not offer financial compensation to any who in obedience to its policy suffered loss. Another disability was that it was prohibited from imposing any regulation, restriction or condition which if an object of the Association would make it a trade union. It was not the Association which had put these restrictive covenants into its memorandum; they were put in by the Board of Trade at the time as part of the limited liability licence. Conversion into a trade union or friendly society or any other organization which could distribute its money amongst its members would mean the winding up of the present Association and the distribution of its assets. One barrier in the way of becoming a trade union was that doctors could not be described as either masters or workmen, so that the ordinary rules and privileges of trade unionism and in particular, immunity from legal proceedings would not apply even if a medical trade union were established. They were neither employers nor workmen within the meaning of the Trade Union Acts and so would get no advantages of collective bargaining by such a recourse.

The proposal which was approved by the Council would go to a Special Representative Meeting at the end of March was that there should be set up by the Association, but independently of it, a new body in the form of an independent board of trustees with power to organize and finance collective action by the profession and to provide financial compensation for practitioners suffering hardship through participation in such collective action. The new body to be entitled the British Medical Guild. "We do not want to see established a body of limited membership. We want to be able to take action if necessary on behalf of any and every doctor in the profession whether a member of the B.M.A. or not. Our membership is big enough to enable us to take that wide outlook. The policy of the profession would be laid down by the B.M.A. as at present through its Representative Body, but the job of enforcing it would be carried out by an independent body appointed by yourselves with full authority to act for you, which would not be under the disabilities to which I have referred. This will be fully discussed at the Special Representative Meeting."

It was also proposed to reorganize the methods of election to the Council so as to have smaller electoral areas and a larger proportion of members of Council directly elected by the constituencies.

These were the major problems which the Association was facing and he hoped that during the ensuing weeks they would receive serious thought from the membership as a whole, and that local meetings would be held at which constructive ideas would be brought forward and representatives duly instructed.

Points Elucidated

In reply to questions Dr Dain said that it would not be possible for the Government to refuse a charter for the proposed Guild, also that such a Guild would not be associated with the T.U.C.

A Member. In saying that it is not possible for doctors to organize themselves into a trade union, does Dr Dain imply that the Medical Practitioners' Union has been living in a fools' paradise?

Dr Dain. The answer is "Yes" (Laughter).

Asked about fees for immunization, Dr Dain said that according to the Act immunization should be carried out by general practitioners. The Act also placed the responsibility for doing it on local authorities. The framers of the Act assumed that it was a general practitioner service within the contract with the local executive council, and that the local authority would pay for the certificate stating that it had been done. But on further study it was discovered that this service was not among those to be provided by the executive council, and therefore the council was not in a position to pay for it, and it was not part of the doctor's contract. The local authorities therefore must pay for the service as well as for the certificate. The argument was not yet concluded.

Another question was on the subject of temporary residents. Dr Dain said that it had not yet been possible to get the Government to move in this matter so as really to start the scheme. But the money would be paid, and the Association was doing its best in the matter.

Further questions related to the Whitley Council. Dr Dain explained that the Association had agreed that a body of the type of the Whitley Council backed by arbitration should be set up for the profession. It had resisted a proposal that the Whitley Council should be one which covered all employees—nurses and others—in the National Health Service. There had been misgivings on the part

of local authorities who discovered that such an arrangement would react upon the salaries to be paid not only to their medical officers of health but to their other principal officers. The Association was taking action to bring about an early decision.

In reply to a series of questions asked by Dr A. C. E. Beach Dr Dain said that the Association had no intention of giving way on the subject of work done, but time must be allowed to discover the exact dimensions of this extra burden of work. That was not possible as yet in the short time during which the Service had been operating. The sample areas surveyed with a view to discovering how far Spens was being implemented were chosen as representative. It was a pure accident that none of them were in the south of England.

On the motion of Dr Frank Gray a very cordial vote of thanks was accorded to Dr Dain for his address.

HEARD AT HEADQUARTERS

Medical Film

The film 'Ancient Pectons' shown by the St. Pancras Division at B.M.A. House recently, was directed by Dr Joseph E. F. Riseman and photographed by the Harvard Film Service, Harvard University. It is a full-length colour film with a sound commentary lasting some 80 minutes and is a useful visual aid to the study of the subject. The film is in four parts—Clinical Characteristics, Physiology, Pathology, and Treatment. The photography is good and the main captions are excellent though the focus of some of the written material might be improved. The clinical manifestations are well described. The experimental physiology section is interesting and the pathological findings x-ray appearances, and dissections of the injected heart are remarkably clear. Treatment is dealt with exhaustively and the author ingeniously depicted and criticized the multiplicity of methods of treatment. A shot showed a multitude of bottles and remedies which were rapidly classified on shelves as of 'Great value', 'Slight value', and 'No value'. Cupboard doors closed over the latter two, and the emphasis was given to the former. Possibly the film is too long, and the expert might complain that it is too elementary, but for a rapid survey of a difficult subject it is hard to see how it could be improved. The student and general practitioner would be particularly interested. It may be borrowed from the B.M.A. Film Library.

Doing Sums

The members of the General Medical Services Committee revealed themselves as quick arithmeticians during an all-day meeting when they discussed remuneration. Sometimes they talked in millions—global figures—sometimes in shillings and pence, sometimes in percentages and at other times in vulgar fractions, but whatever it was it found them mathematically agile. But apart from the calculations two things emerged. One was the statesmanlike approach to the subject of remuneration. It was not a question of bargaining or chaffering but of fully substantiating every figure put forward so that as between a figure which was probably justified but lacked the final verification and a lower figure which could be fortified by actual facts the Committee chose the latter. The other point was the extraordinary amount of time these calculations and discussions have taken. The Committee itself has had 10 special meetings on the subject in addition to its regular ones and the members most closely concerned have been meeting on the average once a week since Christmas, entailing for some of them long journeys. This remuneration argument is no matter of putting two and two together and trying to make it five: there are people at the Ministry who can add up.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

Metropolitan Borough Councils—Fulham, Hackney, Poplar, Nor-Court, Borough Councils—Dartford, Radcliffe (limited to future appointments). WallSEND

Urban District Councils—Denton, Droylsden, Houghton-le-Spring, Hutton-with-Roby, Redditch (restricted to new appointments), Tivdesley.

Correspondence

Graduated Capitation Fee

SIR.—Dr. Charles Hill last night (Feb. 1) gave to the Leeds medical practitioners a clear exposition of what the remuneration of G.P.s under the Act means and what the B.M.A. is doing about it. I went home and considered this remuneration problem once more *ab initio*, and the following argument proposed itself.

The Spens Report says that 50% of the G.P.s should earn £1,300 net or more. Dr. Hill told us that when the meagre 20% betterment factor is added the gross figure for 50% of G.P.s should be £2,613. He also said that the average number of patients available per doctor is 2,200. Assuming that as many doctors practise midwifery under the Act as do not, we can leave midwifery fees out of our calculation, and are then left with the fact that £2,613 divided by 2,200 (or 23s. 9d.) must represent the sum to be paid to a doctor for each patient if the Spens recommendation is to be satisfied. This sum of 23s. 9d. includes capitation fee and superannuation, and shows that even with the small betterment factor of 20% the capitation fee should be more than £1.

Next to rural practitioners, for whom a special mileage grant has already been made, the suburban G.P. is the hardest hit by the new Act, for he usually had a practice smaller than the G.P. in the thickly populated area and yet often had greater expenses. His mileage was greater, and so petrol and car expenses were greater. His rent was often higher, and his patients expected a higher standard of equipment. How, asked Dr. Hill, is it possible to help him? The answer is by using a sliding capitation fee. With the present betterment factor, the capitation fee should be 30s. for the first thousand patients, 20s. for the next thousand, 10s. for the third thousand, 7s. 6d. for the fourth thousand, and 5s. for the fifth thousand. The resulting income would be:

For 1,000 patients	£1,500 gross	
" 2,000 "	" £2,500 "	
" 2,200 "	" £2,600 "	(vide Spens)
" 3,000 "	" £3,000 "	
" 4,000 "	" £3,375 "	

This method of remuneration would tend to reduce the lists of those doctors who have more patients than they can adequately attend.

Another problem which is looming ahead is that of correlating the small expenses of doctors working in the new health centres with the large expenses of doctors working from their own rooms in the transitional period when health centres are slowly coming into action. The only fair way is to pay the doctor's expenses at his own rooms and then deduct the same amount as the doctor pays for his rooms in the health centre. It looks a big problem.

My final thought is that the adopted method of remuneration provides a financial stimulus to the G.P. to treat as many patients in a given time in the cheapest surroundings with the cheapest equipment, and I think the profession could well give thought to obviating this by a sliding scale such as I have outlined, remembering that it is based on a 20% betterment factor which is out of date and should be increased to be comparable with the increase in cost of living.—I am, etc.,

Leeds

R. A. MURRAY SCOTT.

Reflections on N.H.S.

SIR.—All of us, I am sure, will thank Dr. R. W. Cockshut for his "Reflections on N.H.S." (*Supplement*, Jan. 29, p. 46), and for telling us at last many of the secrets behind the negotiations. This secrecy of negotiation behind an iron curtain has been one of our main dissatisfactions with the B.M.A., for we have not appreciated being treated as children not yet reached age of discretion, especially in a matter which has affected the whole of our lives. But now that we know the truth we can feel grateful to those who fought for us, and grateful that so much has been won to make our lives more bearable than they might otherwise have been.

Dr. Cockshut, however, claims certain gains which I personally consider were lost opportunities for altering certain conditions of

service to our advantage. I quote from his article under the heading "Our Gains":

"4. G.P.s are in full and free competition (inside a State service)." There are those of us who hold the considered opinion that a salaried service is not only desirable but even necessary from two aspects: (a) the ethical, because we believe that competition can lead to exploitation by the doctor of bedside manner (salesmanship), or exploitation of the credulity and superstitions of many patients; and (b) the practical, because competition is the economic lever which impels us to be slaves to a 24-hour and 7-day service, a state of affairs which is now an anachronism.

A rota of duty shared by neighbouring practitioners without fear of loss of income (as would obtain in a salaried service) would show an improvement in our health and in our tempers, and also, in direct proportion, in the quality of our work and in the enjoyment of it. It is no doubt extremely gratifying to our patients to have us at their beck and call at every hour of day and night, but let it be understood that under present conditions the G.P. no longer has an incentive to work these long hours of duty. The N.H.S., as I understand it, sets out to provide adequate medical service for all and sundry, without need of financial considerations. This condition would be adequately provided for by a duty rota. It is the B.M.A. which has insisted on the retention of free choice of doctor, and in a salaried service such free choice would obtain during an 8-hour-duty day, but outside these hours the patient would have the services of the doctor on duty. Why not? After all, when a patient is admitted to hospital he does not expect free choice of consultant, nor in practice does he have it. Why therefore should he expect free choice at all times from the G.P. section of the profession? Was not that merely a tradition deliberately engendered by the competition of private practice?

"5. . . and there is no chance of doctors being crammed into health centres before the merits of these have been assessed." "6. We practise in our premises and cannot at any time be forced into a health centre."—An important point here is to ascertain whether Dr. Cockshut is in active general practice at the present time. If he is not, then he can hardly be expected to appreciate the practical difficulties (as opposed to the theoretical) of trying to give a 24-hour service without domestic help in our homes, or to understand that this can in fact only be done at the price of the G.P.'s health and of that of his wife. Living-in domestic help is now unobtainable except in the form of a married couple or of a mother and child, neither of which can many of us afford either in money or accommodation. Daily domestic help, or that of a secretary, is obtainable from 9 a.m. until 5 p.m., but at a wage quite beyond the financial ability of most G.P.s, so long as we are paid at the 1939 value of money while labour is employed at the 1948 value. And these ladies do not work at week-ends. But I can assure Dr. Cockshut that the G.P.'s telephone rings long before 9 a.m. and continues to ring long after 5 p.m., nor is it altogether silent on Saturdays and Sundays. Bearing these facts in mind, I can assure him also that the G.P. awaits with anxiety and anticipation the provision of health centres, and that it would need no force whatever to make them use them.

On this point it would be enlightening to ask the G.P.'s wife to what extent she enjoys having no peace or privacy day or night in what should be her own home either on week-days, at week-ends, or holidays; having her home invaded by any stranger at any hour; having her meals and her sleep disturbed; having to leave the toast to burn and the milk to boil over and the baby to scream in the middle of its feed while she tires her already weary feet in order to answer the telephone or door-bell, as often as not for some quite fatuous reason. Ask her, in fact, how she likes having an office in her home—not just for eight hours, mark you, but during every hour of every day all through the year except holidays. Ask her how she enjoys having a husband whose mind never can be at rest, whose plans are always uncertain, and a home which can never be a home at any time, etc.

Sir, it is my contention that the present hours of duty expected of the G.P. should be altered because they are no longer necessary; that the N.H.S. gives us, for the first time, the conditions under which it is possible to better them; and that this change could be effected by the introduction of a salaried service and by a salaried service only.

Should we ever obtain the beatific working conditions which I envisage, the G.P. could then live at least five miles away from his practice and so be spared the constant interruption of his private life by matters which could be dealt with perfectly adequately by the duty doctor. In fact, had the Minister of Health (in spite of the B.M.A.) given us this inestimable boon many of us, and particularly our wives, would have lived to bless the name of Bevan.

After six months' experience of the N.H.S. I think it essential that a plebiscite should now be held among G.P.s on this point of the desirability of a salaried service so that the medical

negotiating powers could be conversant with the present views of the rank and file of the profession which they represent. Let the G.P. decide for himself whether the freedom gained for his private life would not in fact outweigh all the theoretical disadvantages of a salaried service.

No doubt our patients would not approve at first of the new system, but in time they would get used to it; and when they find that medical help is always at hand in the form of a duty doctor they would not resent the new-won freedom of the doctor and his wife. I feel sure of this, for if nothing before has proved it the N.H.S. has proved, anyway to me, the fundamental consideration of the vast majority of patients when they understand our working conditions and what they mean. As regards the inconsiderate type of patients, who are in the minority, I see no reason for us to pander to their selfishness.—I am, etc.,

Englefield Green, Surrey

W. E. R. BRANCH.

* In answer to a question put in the above letter, Dr. R. W. Cockshut is in active general practice.—Ed., *B.M.J.*

SIR,—I am glad to see that Dr. R. W. Cockshut's conscience is troubling him (*Supplement*, Jan. 29, p. 46) about the part he played in delivering up the profession bound hand and foot in that he finds it necessary to defend it publicly twice in a fortnight. His apology is more accurate on paper than in practice—e.g., local authorities may be banished but many familiar faces survive on management committees.

"We have the absolute right to set up in any part of the country. . . ." Has he tried? Is he aware of the 200 or so applications for each vacancy advertised?

"There will be no capital financial difficulty. . . ." In the bad old days an impecunious doctor could borrow £4,000 and be assured of an immediate income of £2,000 out of which he could live comfortably while repaying the loan. Now, according to Dr. Cockshut, he can set up and be assured of at least £300 per annum for the first year and maybe three times that amount in the second. How does he exist in this period, let alone rent a surgery or buy a car? The buying and selling of practices in a 100% scheme is logically indefensible and could never have been upheld against any political party, but that does not help the unfortunate doctor wishing to set up in practice.

"The decision to hold an immediate plebiscite was one of the wisest the Council took. . . ." He is certainly in a minority there. Most people would agree that it was this action which precipitated the landslide.

"The financial side will be remedied very quickly. . . ." What about the consultants and specialists, who, having lost their private practice, will receive only token payments for at least a year?

I agree with his remarks about losing the initiative; this was a worse tactical error than the second plebiscite. The fundamental and almost irretrievable error was in not getting satisfactory terms of service in black and white before agreeing to enter the Service. Any "well-informed doctor" or one with experience of bureaucratic medicine—e.g., in the Services—could have told him that on entering the Service one surrenders practically 100% of one's bargaining ability. The dentists took care not to enter until they were assured that their terms would be at least financially satisfactory. That this was probably due to a miscalculation on the other side is shown by the fact that their incomes have now been statutorily limited. Whatever one may say or think about the high calling of medicine and sordid financial gain, one cannot attend to the former with a pocketful of unpayable bills, and unless financial security is assured Mr. Bevan will very soon dance on our collective grave.—I am, etc.,

Bexley, Kent.

G. DALLEY.

Openings for Practice

SIR,—Dr. R. W. Cockshut (*Supplement*, Jan. 29, p. 46) has placed his finger on a spot that may become gangrenous in time. The tyranny of the Act will not be exercised by any Minister of Health but by members of our own profession. I think Mr. Bevan genuinely intended that there should be free movement of doctors except inside specially defined areas.

This intention is being thwarted and will be thwarted by the selfishness of local medical committees.

The cumbrous process by means of which a practice can change hands is likely to serve as a medical preserve in most areas. The young doctor is finding it increasingly difficult to settle anywhere. Men who for health reasons or family reasons wish to change into other areas either find themselves in a queue or the post is filled by a favoured nominee of the local medical committee. Everywhere committees are hastening to assure the Minister that their area is over-doctored in case their own lists might become smaller. The liberty of the profession is not being threatened by the Minister of Health but by the members of our own profession. We all know this is so in our own areas.

It is time that a survey is made of the whole of medical practice and—according to the population—openings made, irrespective of local opinion, for all the doctors who are seeking practices. If something of this sort is not done everyone will live and die in the same neighbourhood whether he is successful or unsuccessful. We made a vital mistake in giving up the goodwill of our practices, and our own brethren are riveting the chains with which we have bound ourselves.—I am, etc.,

Cambridge.

A. E. MOORE.

Superannuation and Spens

SIR,—It has been stated in the *B.M.J.* that the State's contribution of 8% of the assumed net income is taken into account in arriving at the true remuneration re implementation of the Spens Report. If this is so, it surely is essential that the superannuation regulations be amended so that, if a doctor dies or retires within five years of entering the National Health Service, he or his executor is refunded the State's contribution in addition to his own, with, of course, interest compounded on both sums. If the State's contribution is not so returnable, it then is certainly not deferred income for the unfortunate doctor who does not do five years' service.—I am, etc.,

Wolverhampton.

LLEWELLYN C. RUTTER.

Fee for Service

SIR,—After reading Dr. R. W. Cockshut's letter (*Supplement*, Jan. 8, p. 16) recommending resignation if there is any more talk by the Ministry of the totally inadequate 20% betterment factor, and that we discard Spens if it does not give us at least a 30s. capitation fee, I was amazed to read his apologia for the B.M.A. (*Supplement*, Jan. 29, p. 46) and claim for a limited victory as a result of the Representative Body's surrender to the Minister. Most of the claim has been already shown as hollow or of questionable value by subsequent experience.

As to the betterment factor, what confidence can be placed in the B.M.A. economic expert's figure of 185% as compared with 1938? This calculation does not even include the cost of buying and running a car. One might as well control the price of steel taking no account of the increased cost of coal, materials, equipment, and labour since 1938. Again, large numbers of us do not own houses or have had to buy at post-war prices. A doctor should have an abode corresponding with the dignity of his profession, and this item must be included in the increased cost of living. The index assumption-controlled rents of houses and surgeries, and denies that the effect of post-war prices would be large.

When I read the various suggestions for increasing the capitation fee for the first thousand, weighting it for the old and the very young, and for inducement fees in certain areas, I feel how indissolubly complicated the capitation system must become yet still be unfair. No matter what capitation fee we receive—and we can be sure it will never be adequate from previous experience—our reaction to the capitation patient will always be that inspired by the insufferable nuisances we have on our list. Eliminate all this by an adequate fee for service plus a substantial addition by the patient and we will be paid in proportion to our work. In the country districts a mileage scheme will continue to operate.

I wrote to the Member for Dorset East challenging the Conservative Party, if re-elected, as champions of private enterprise and initiative, and freedom of the individual, to withdraw the compulsory weekly levy on the self-employed, saying that it

was universally detested. He replied that, while in favour of a national health service, the present Act went too far and he felt that a Conservative Government would bring in an amending Bill, but that one of the difficulties was the difference of opinion among medical men. He did not want doctors to be in the power of any Government, and having had experience of State medical services did not like them, except in special cases to meet special conditions. This was a reasonable answer under the circumstances, and I can only hope that most other general practitioners will seize the opportunity without delay to put the same question to their Conservative member or prospective candidate.—I am, etc.,

Bournemouth.

A. R. THATCHER.

The Stream of Specialists

SIR,—In the course of one's hospital career one has seen many men spend some of the most valuable years of their lives preparing themselves for the career of a consultant only to find that the way was blocked by lack of a "vacancy on the staff." Some of the best have been frustrated after years of hard struggle and have naturally become embittered. A feature of present-day hospitals is the large number of clinical assistants, first assistants, and registrars who are already upon the lower rungs of the consultant ladder. A glance over the advertisements in the *Journal* shows that apparently there is an ever-increasing number of these appointments—more than a year ago. There is also a great increase in the numbers of candidates for the higher qualifications. Even allowing for a vast increase in the posts for fully qualified specialists it is impossible to avoid a strong suspicion that in a few years there will be a large number of the brightest young doctors doomed to disappointment in their career.

The problem demands urgently the study by experts on staffing problems in order to promote a steady flow of the required number of consultants and to prevent the formation in a few years of a pool of the cleverest (not necessarily the best) young people in the profession engaged in internecine strife for promotion. It is not a medical problem, and it is really the duty of the Ministry (on grounds of economy alone) to see that this is done. Unfortunately it is open to the cynical to say that general practice is at any rate open to the unsuccessful would-be consultant, but this cannot be accepted at the present day, for their services are wanted in general practice about one year after qualification, not ten years after, when they will have become discontented specialists who have forgotten much of medicine away from their specialty. It may even be difficult for such to get into general practice at that period. It is not too easy to-day.

It is a much more urgent problem than the provision of easy-chairs in out-patient halls. It demands that the policy of the Ministry on future staffing of hospitals (if there is such a policy) be put on the table and submitted to the examination of medical and lay experts.—I am, etc.,

Helensburgh, Dunbartonshire.

A. E. BARNES.

Association Notices

PROPOSED ALTERATION IN DENBIGH AND FLINT DIVISION

Notice is hereby given by the Council of a proposal to form two Divisions in the place of the present Denbigh and Flint Division as follows:

The East Denbigh and Flint Division: the area of the present Denbigh and Flint Division to the east of the Clwydian Range.

The West Denbigh and Flint Division: that part of the present Denbigh and Flint Division which lies to the west of the Clwydian Range, with the addition of Colwyn Bay, and Colwyn, and Rhos-on-Sea.

Any member affected by this proposal and objecting thereto should write to the Secretary of the Association not later than Feb. 26, 1949.

CHARLES HILL,
Secretary.

ELECTION OF MEMBERS OF THE COUNCIL BY BRANCHES NOT IN GREAT BRITAIN OR NORTHERN IRELAND

As a result of the nominations received for the election of members of Council by Branches overseas the following have been elected for the three years 1949 to 1952:

Branches within the area of the Medical

Association of Eire	P. T. O'Farrell, Dublin.
South Australian, Tasmanian, Victorian, and Western Australian ..	J. H. Anderson, Ruthin.
New Zealand and Fiji	J. A. Stallworthy, Oxford.
Hong Kong and China, Malaya ..	J. S. English, Newtownards.

The following candidates have been nominated for the Branches named:

West Indian Branches	H. B. Morgan, London. J. B. W. Rowe, Harrow.
Grouped African Branches	L. R. Broster, London. P. C. C. Garnham, Farnham Common.

Voting papers will be issued to all the members in these two Groups.

No nomination has been received in respect of the New South Wales and Queensland Branches.

CHARLES HILL,
Secretary.

Diary of Central Meetings

FEBRUARY

- 22 Tues. Committee on the Postgraduate Education of General Practitioners, 2 p.m.
- 24 Thurs. Occupational Health Committee, 2 p.m.
- 24 Thurs. Committee on Psychiatry and the Law, 2 p.m.
- 25 Fri. Film Committee, 2 p.m.

MARCH

- 1 Tues. Health Centre Committee, 2 p.m.
- 2 Wed. Dawson Williams Memorial Fund, 11.30 a.m.
- 2 Wed. Private Practice Committee, 2 p.m.
- 3 Thurs. Special Conference of Representatives of Local Medical Committees, 10 a.m.
- 3 Thurs. Special Meeting of Council, 6 p.m.

Branch and Division Meetings to be Held

CAMBERWELL DIVISION.—At St. Giles Hospital, London, S.E., Tuesday, Feb. 22, 8.30 p.m. Clinical meeting.

CHELSEA AND FULHAM DIVISION.—At Fulham Town Hall, Friday, Feb. 25, 8.30 p.m. for 8.45 p.m. Special general meeting. Address by Dr. L. S. Potter on the latest developments in the N.H.S., with special reference to the reorganization proposals recommended by the B.M.A. Council. Time will be allowed for discussion and questions.

GUILDFORD DIVISION.—At Royal Surrey County Hospital, Guildford, Friday, Feb. 25, 8.30 p.m. Address by Lord Horder: "Where Do We Go From Here?"

HASTINGS DIVISION.—Special meeting announced in *Supplement* of Feb. 12 (p. 80) to be held on Feb. 20, 3 p.m., has been postponed until March 20, 3 p.m.

HASTINGS DIVISION.—At Royal East Sussex Hospital, Thursday, Feb. 24, 8 p.m. Mr. F. T. Moore: "Plastic Surgery."

HENDON DIVISION.—At Hendon Hall Hotel, Tuesday, Feb. 22, 8.30 p.m. Combined address and demonstration by Dr. P. E. Thompson Hancock and Mr. Reginald Ledlie: "Early Diagnosis of Cancer of Stomach." Illustrations by colour cinematography and lantern.

LEIGH DIVISION.—At Boar's Head Hotel, Leigh, Tuesday, Feb. 22, 8.30 p.m. Joint meeting of Leigh and Wigan Divisions. Address by Dr. E. E. Claxton on the present position under the National Health Service, including remuneration and the trade union issue. Discussion and questions will follow.

LEWISHAM DIVISION.—At St. John's Hospital, Morden Hill, Lewisham, London, S.E., Sunday, Feb. 20, 11 a.m. Clinical meeting.

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, Feb. 24, 7.15 p.m., Clinical demonstration by Dr. C. N. Armstrong: "Hypopituitarism Following Postpartum Haemorrhage (Simmonds's Disease)." 8.45 p.m., address by Mr. C. Gordon Irwin: "America, 1948."

WESTMINSTER AND HOLBORN DIVISION.—At Postgraduate Medical School of the Royal Free Hospital, Onslow Gardens, Fulham, S.W., Wednesday, Feb. 23, 8.30 p.m. Dr. M. Lederman: "Cancer of the Cervix." Open to all medical practitioners in the area of the Divisions.

WIGAN DIVISION.—At the Hollies, Wigan Lane, Wigan, Thursday, Feb. 24, 8.15 p.m. Lecture by Dr. R. S. Taylor: "The Diagnosis and Treatment of Heart Disease." A short general meeting will follow.

The permanent offices of the Fellowship for Freedom in Medicine are now established at 45, Nottingham Place, London, W.1.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY FEBRUARY 26 1949

PAIN IN CHILDBIRTH

REPORT OF THE SUBCOMMITTEE OF THE MEDICAL WOMEN'S FEDERATION*

This subcommittee was set up by the Council of the Medical Women's Federation at its meeting in Bournemouth in October, 1947. In the course of correspondence in *The Times* during August and September, 1947, one correspondent had suggested that only married women doctors with children of their own could speak with authority on the need or otherwise for anaesthetics in childbirth, and inquired whether any concerted and thorough study of the whole question had ever been undertaken. This subcommittee was set up with the object of obtaining information on that point.

Method of Investigation

At its first meeting the subcommittee concluded that it was important to collect the necessary information as quickly as possible. It was thought that this information could best be obtained by means of a questionnaire to married medical women. It was decided to question only those whose youngest child was not more than 10 years old. As a preliminary step, a "pilot" questionnaire was sent out to about 300 medical women. The subcommittee is satisfied that the questionnaires were sent to a representative sample of medical women with children under 10 years. Names and addresses were supplied by members of the subcommittee and from information available at the headquarters of the Medical Women's Federation. It was felt by sending out questionnaires rather than by inviting those interested to apply for them, that a more satisfactory cross-section would be obtained of the group from which information was desired.

The questionnaire consisted of two parts, the first containing three general questions on relief of pain in childbirth and the second consisting of a separate sheet for each confinement on which details of childbirth and of the methods of relief given were requested.

The response to the questionnaire proved disappointing and only 196 replies are available for analysis. However, a great deal of valuable information has been derived from the existing replies, and the subcommittee feels that no useful purpose would be served by any extension of the present inquiry. An inquiry designed to include all medical women with children would entail sending a questionnaire to all medical women, since there is no means of knowing which of them are married and which of those who are married have children. The response could not be expected to be great enough to justify the expense of an extended investigation of that kind.

*The members of the subcommittee were Professor Lucas Keen and Dr. Annis Gillie (ex-officio), Miss Josephine Barnes (chairman), Dr. Barbara Bailey (hon. secretary), Dr. K. K. Conrad (medical statistician), Dr. Enid Hughes, Mrs. Handfield Jones, Dr. K. G. Lloyd Williams, Dr. Mary Macaulay, and Miss D. Anderton Sharpe.

STATISTICAL ANALYSIS OF SOME REPLIES TO THE QUESTIONNAIRES

BY

K. K. CONRAD, M.B., B.S., D.P.H.

Out of approximately 300 questionnaires sent to medical women, 196 replies were received, giving details of 425 confinements. Of these 221, or approximately 52%, took place within the past five years, and 345, or approximately 81%, took place within the past ten years. Details of these are given in Table A below and also in Table VI. Of the 196 replies, two did not

Table A

Date of Birth	Number of Delivery				
	1st	2nd	3rd	4th and 5th	Total
1943-48	82	7	42	22	221
1939-43	67	20	15	2	124
Before 1938	44	23	9	4	80
Total	193	50	66	28	425

give details of the first delivery and one has been excluded as it occurred over 20 years ago.

The replies to the three general questions are analysed in Tables I, II, and III.

Table I.—Do You Consider that Relief of Pain in Childbirth is Necessary?

Yes	178	Unsure	1
No	8	No reply	1
Sometimes	6		

Thus 184 out of 196 medical women who have had children are in favour of relief of pain in childbirth.

Table II.—After your First Confinement Did You Dread a Second?

	Type of First Confinement		Total
	Normal	Abnormal	
Yes	18 (14%)	16 (25%)	34
No	169 (86%)	42 (65%)	141
No reply	5	6	11
Total	192	64	256

Table II has been divided for obvious reasons, into normal and abnormal first confinements. Only 14 of mothers having a normal first confinement and 25% of those having an abnormal first confinement dreaded a second.

Table III.—Did You Find that the Memory of Pain in Childbirth Faded Quickly?

Yes	11
No	61
No reply	4
Total	76

The replies to the questions on individual confinements were tabulated into tables numbered IV to XVII. Some of this material has been discarded, as will be indicated in the statistical analysis. There were two main reasons for discarding material: in some cases the information received did not appear to be relevant to the present inquiry, while in other cases the small numbers falling under each heading were inadequate for any conclusion of value to be drawn.

Tables IV and V dealt with abnormalities of pregnancy and with length of labour and reasons for induction of labour where this was performed. The material obtained was too diffuse for any useful conclusions to be drawn from it.

Tables VI and VIa deal with the method of delivery. The most notable feature is the high incidence of forceps delivery.

Table VI.—Analysis of Deliveries

No. of Delivery	Normal*	Abnormal*				All Deliveries
		Forceps	Complicated Breech	Caesarean	Total Abn.	
1st	130	54	1	8	63	193
2nd	123	10	—	5	15	138
3rd	58	6	—	2	8	66
4th	21	1	—	1	2	23
5th	4	—	—	1	1	5
Total	336	71	1	17	89	425

* Twins are counted as one delivery and included in the appropriate normal or abnormal group.

Table VIa.—Analysis of 54 Forceps Deliveries in 1st Group of Table VI

Reason not stated	26
Persistent occipito posterior	11
Uterine inertia	4
Deep transverse arrest of head	1
Foetal distress	2
On after-coming head	2
Face presentation	1
Disproportion	2
Impacted head	1
Cord round neck	1
Prolapsed haemorrhoids	1

The average age of the mothers in this group was 31½ years.

in first births, 54 out of 193, or approximately 27% (standard error (S.E.) 3.2) of first babies, being delivered with forceps. The average age of mothers in this group was 31½ years—slightly higher than the average age of mothers achieving a normal first delivery, which was 29 years. Table VIa shows an analysis of the reasons for forceps delivery, but the large number, 26, who gave no reason for the application of forceps prevents any conclusion being reached.

Table VII, which dealt with abnormalities in labour, was discarded as of no value.

Table VIII deals with the place of confinement.

Table VIII.—Analysis by Place of Confinement

Place of Confinement	Number of Deliveries									Total
	1st		2nd		3rd		4th and 5th			
	Normal	Abnormal	Normal	Abnormal	Normal	Abnormal	Normal	Abnormal

House-surgeon									
Born before arrival			2		1		1		3
Total	130	63	123	15	58	8	25	3	336

Obstetric specialists attended at the delivery in 6 normal births and 89% of abnormal births. An obstetric specialist was engaged by almost all those delivered by wives, but was unable to reach the mother in time to the child.

Table X dealt with the presence or absence of an anaesthetist and the time of his or her arrival. The reply to this question were inadequate to permit of analysis, and the table is therefore discarded.

Table XIa deals with anaesthetics given during labour.

The bulk of anaesthetics were given in the second stage of labour, those by far the most commonly used being chloroform.

Table XIa.—Anaesthetics in Stage 2 of Labour. Total Deliveries

100% of abnormal births received anaesthetics: a completely satisfactory, b helpful, c, useless.

Classification of Anaesthetics in Table XIa—In general the entries are classified under the main anaesthetic. The ether group includes all gas, oxygen, and ethers. Gas-and-oxygen—given almost entirely by anaesthetist. Gas-and-air—usually given by patient herself. "Trilene"—trichlorethylene. The basal anaesthetics were "Avertin" (brometh and paraldehyde). Thiopentone (pentothal) was given intravenously.

gas-and-oxygen, and gas-and-air. It must be noted that a high proportion of the births in this series took place before the introduction of analgesia with trileine.

Women doctors speak almost unanimously of the efficacy of chloroform given at this time. Out of 222 who received it 194 found it perfect; 24 of the remaining 28 found it helpful, leaving only four dissatisfied with its effects.

There is a suggestion that gas-and-air, administered in nearly every case by the Minnitt apparatus, was slightly more effective in the first stage of labour (see Table Xib), where 43% found it completely satisfactory, than in the second stage, where it achieved that degree of efficiency in only 34% of cases. There is a strong suggestion among the replies to the questionnaires that in the case of gas-and-air and gas-and-oxygen given in the second stage of labour the efficacy of the anaesthetic agent was greatly enhanced when administered by a trained anaesthetist. There are thus three variables—the type of anaesthetic, the experience of the anaesthetist, and the time at which it is given.

Table Xib shows that most of the sedatives and analgesics were administered during the first stage of labour. In the second stage of labour the effect of these drugs is often overshadowed by the additional effect of an anaesthetic. Investigation has therefore been limited to those given in the first stage.

In general, as would be expected, there is a pronounced decrease in the use of these drugs in increasing birth orders.

The sample is a small one, but there are two suggestive series of figures.

First, marked dissatisfaction is expressed with the effects of potassium bromide and chloral, the colloquial "mothers' mist." Out of 80 mothers who received it, 38, or approximately one-half, found it useless, and another 28 found it merely helpful, leaving only 14 who were entirely satisfied with it. Secondly, there is a suggestion that derivatives of opium were more helpful than morphine in a pure state—4 out of 31, or nearly 1 out of 8, finding the former useless, while 10 out of 40, or 1 in 4, found morphine itself useless.

Those who did not reply and had abnormal births all had caesarean sections. In the case of 336 normal deliveries, 53 mothers (16%) were left alone longer than they liked. Out of 89 abnormal deliveries, 12 (13%) made the same complaint. No cause for complaint in this respect was found in 83% of normal and 73% of abnormal labours. Of the 65 mothers who answered "Yes" to this question 40 were in the first stage of labour, 12 in the second stage and 11 at the end of the first stage and the beginning of the second.

Table XIII dealt with the question, "Were you made to walk about at any stage of your labour when you would have preferred to lie down? If so, when?" This table is not given, but the replies received showed that few of the mothers had any cause for complaint in this respect.

Table Xib.—Sedatives and Analgesics in Stage I of Labour. Total Deliveries

a, completely satisfactory b, helpful c, useless

Classification of Drugs in Table Xib—The hyoscine group includes scopolamine. The morphine and hyoscine group includes all "twilight sleep." The barbiturates include "amytal," barbital soluble ("medinal"), "seconal," "hebaral sodium," thiopentone sodium, thiopentone (not intravenous), and pentobarbitone soluble ("nembutal"). The opium derivatives include "opoidine," "omnolon," "nepenite," and tincture of opium. Heroin=diamorphine. The chloral group includes chloral and potassium bromide ("mothers' mist") and chloral hydrate.

Wanted more relief, % total births	27%	36%	29%	25%	21%	24%			

N = normal, Abn. = abnormal

Table XIV deals with the question, "Would you have liked more complete relief?"

A rather large proportion seemed dissatisfied with the relief afforded them during their deliveries, particularly in view of the fact that 148 out of the 193 first deliveries were conducted

by obstetric specialists and that medical women know what to expect when labour starts. This proportion was higher in the first stage of labour among the abnormal deliveries (36% compared with 27% in normal labours), but lower in the second stage. This is almost certainly due to the fact that in the second stage 100% of abnormal deliveries were conducted with an anaesthetic, compared with only 90% of normal deliveries.

Tables XVa and XVb deal with the question of perineal repair.

The answer to the first part is that a large majority of the medical women who completed the questionnaire are in favour of relief of pain in childbirth. Table I shows that 184 out of 196 replied "Yes" or "Sometimes" to the question, "Do you consider that relief of pain in childbirth is necessary?" while only 8 answered "No."

The detailed investigation of the various aspects of childbirth has yielded less definite information. This is due to

Table XVa.—Perineal Repairs

Type of Anaesthetic	1st Delivery		2nd Delivery		3rd Delivery		4th Delivery		5th Delivery		All Deliveries		Total
	Normal	Abnorm	Normal	Abnorm	Normal	Abnorm.	Normal	Abnorm.	Normal	Abnorm.	Normal	Abnorm.	
General	55 (1)	48	40 (1)	7	14	2	2	—	—	—	111 (2)	57	168
Local	9 (2)	—	6 (2)	—	—	—	—	—	—	—	16 (4)	—	16
None	8 (1)	—	5 (1)	—	5 (1)	—	—	—	—	—	18 (3)	—	18
Total	72 (4)	48	51 (4)	7	19 (1)	2	3	—	—	—	145 (9)	57	202

Average age of mother	29	31	32	—	35	—	—	—	—	—	32	31	

The numbers in brackets received inadequate anaesthetization

Table XVb.—Perineal Repairs. Approximate Percentage of Total Births, Excluding Caesarean

Type of Delivery	1st Delivery	2nd Delivery	3rd Delivery	4th Delivery	5th Delivery	Total Deliveries
Normal .. .	55% (S.E. 4.4)	41% (S.E. 4.4)	33% (S.E. 6.2)	14% (S.E. 7.8)		43% (S.E. 2.7)
Abnormal .. .	87% (S.E. 4.5)	70% (S.E. 15.3)	33% (S.E. 21)			79% (S.E. 4.8)
Total .. .	69%	44%	33%	14% (—)	Nil	50%

The position with regard to anaesthetization for perineal repair seems to be satisfactory on the whole. A general or local anaesthetic was given in the majority of cases and only 6 out of 184 mothers were dissatisfied. In the 18 cases where no anaesthesia was given only three expressed dissatisfaction.

A large proportion of the mothers required episiotomy or suffered perineal tears (see Table XVb): 55% (S.E. 4.4) of normal first births, 41% (S.E. 4.4) of normal second births, and 33% (S.E. 6.2) of normal third births. The average age of these mothers who required perineal repair was 29, 32, and 35 years respectively. Abnormal deliveries showed a higher incidence. In the larger sample, taking all normal deliveries together, the percentage requiring perineal repair was 43 (S.E. 2.7).

Tables XVI and XVII dealt with the two questions, "Did you take any special steps in this pregnancy in order to diminish pain in childbirth? If so, what?" And, "Did you practise antenatal exercises for this purpose; if so, do you think they were of value?" The majority of the mothers answered "No" to these questions, and it is felt that not enough information was received from the replies to make it worth while to give those tables in full.

GENERAL NOTE.—With the exception of the differences between normal and abnormal cases shown in Table XVb, none of the differences noted as suggestive are statistically significant. In other words, the trend of the differences is suggestive but they could in fact be due to chance alone. The present sample is too small to minimize the effect of chance on the results of the analysis.

Conclusions

This subcommittee was set up with the object of obtaining the opinion of women doctors who had children of their own on the need or otherwise for relief of pain in childbirth. It was also asked to carry out a concerted and thorough study of the whole question. The only possible method of carrying out such an investigation was by a questionnaire, a method which is immediately limited by the number who reply. Although the numbers are relatively small, there is reason to suppose that the sample is representative and that certain definite conclusions can be drawn from the results.

two factors—the small numbers in the sample and the highly complicated nature of the problem. The investigation has shown the great diversity of drugs and anaesthetics used for analgesia and anaesthesia in labour. New analgesic and anaesthetic agents are being continually discovered and used in obstetric practice. It is noteworthy that very few of the medical mothers received pethidine and trilete, both agents which have found great favour in obstetric practice in recent years and which are now used to a large extent in many obstetric departments. It is therefore probable that if this investigation were repeated in ten years' time the picture from the point of view of actual analgesics and anaesthetics would be very different. In the present investigation, however, much of the information received from the detailed studies is highly suggestive.

It is found that the majority of the medically qualified mothers did not dread a second confinement even after an abnormal first confinement (Table II) and that over two-thirds (Table III) found that the memory of pain in childbirth faded quickly.

The striking feature of Table VI, which analyses the method of delivery, is the high proportion delivered by forceps. This stands in contrast to the relatively low caesarean section rate. It is not possible to analyse the reasons for the large number of forceps deliveries—54 out of 193 first labours—though it may be accounted for in some cases by demand for delivery from the mothers themselves or to over-anxiety on the part of the attendant.

Table VIII shows that the majority of the confinements took place in the private wards of hospitals or nursing homes, only 28% of mothers being confined in their own homes. Table IX, which deals with the professional attendant, shows that the majority of the mothers engaged an obstetric specialist for their confinements.

Two highly suggestive facts emerge from Table XI, which deals with anaesthetics given during the second stage of labour. Women doctors are almost unanimous in their

praise of chloroform, though, as previously mentioned, the majority of these births took place before trilene came into wide use for obstetric analgesia. The presence of a trained anaesthetist appeared to enhance the effect of gas-and-air or gas-and-oxygen.

Table XIb deals with sedatives and analgesics, mostly given during the first stage of labour. A suggestive fact here is the almost universal dissatisfaction with potassium bromide and chloral mixtures. There is also the suggestion that derivatives of opium itself, such as tincture of opium and papaveretum (omnopon, opoidine) are more effective than morphine in the pure state. The small numbers in each group preclude any further conclusions from this table.

Table XII deals with the question, "Were you left alone longer than you liked?" The answers showed that only 65 mothers out of 409 who answered this question had any complaint in this respect, but those who answered "Yes" felt very strongly about the matter.

Table XIII dealt with the question, "Were you made to walk about at any stage of your labour when you would have preferred to lie down?" The replies showed that only a few mothers had any complaint in this respect.

Table XIV deals with the question, "Would you have liked more complete relief, and, if so, when?" The replies showed that a rather large proportion of the mothers would have liked more relief. This may be partly explained by the fact that there is as yet no safe method of analgesia which is completely effective in all stages of labour—a point which only serves to stress the need for continuing research into methods of relief of pain in childbirth. The majority of these labours were conducted by obstetric specialists, who are likely to be familiar with the best available methods of relief and to offer them to their patients.

Tables XVa and XVb show that the situation with regard to perineal repair is on the whole satisfactory. Tables XVI and XVII dealt with antenatal exercises and preparation for childbirth. Unfortunately the information gained from these tables was inadequate. While there is a real need for information on these points, it could be gained equally well from mothers who are not medically qualified.

The subcommittee feels that this investigation has yielded some important information and has also indicated possible lines of future investigation into the conduct of childbirth. As stated earlier, it is not felt that any extension of this particular investigation would be worth the work and expense involved. This report is presented as fulfilling, at least partly, the terms of reference of the subcommittee and in the hope that it will prove of value.

It is fully realized that the medical mothers studied in this report represent a specially privileged group and that the type of obstetric care they received cannot, at any rate for many years, be made available to all mothers. It is well known that even when elaborate equipment is not available a doctor or midwife can safely relieve much of the suffering of childbirth. In spite of this, the scope and availability of obstetric analgesia in the country as a whole leave much to be desired. The medically qualified mothers in this series are, with few exceptions, emphatic in their opinion that relief of pain is necessary in childbirth, and it is hoped that it will not be long before adequate means of relief are made available to all mothers.

Summary

The Subcommittee on Pain in Childbirth was set up by the Council of the Medical Women's Federation to obtain information regarding relief of pain in childbirth from married women doctors with children of their own.

A "pilot" questionnaire was sent to about 300 medical women, and 196 replies were received from those whose youngest child is not over 10 years of age.

Analysis of the replies shows that women doctors who have themselves had children are almost unanimously in favour of relief of pain in childbirth.

It was found that in the majority of cases the mothers did not dread a second confinement, and also that the memory of pain in childbirth faded quickly.

Analysis of the method of delivery showed a high incidence of forceps delivery in primigravidae. No adequate explanation can be given for this.

Analysis by place of confinement and by professional attendant showed that the majority of medical women are confined in private wards of hospitals and nursing-homes and the majority are cared for by obstetric specialists.

Analysis of anaesthetics given mainly in the second stage of labour shows that this group of medically qualified mothers found chloroform by far the most effective anaesthetic agent. It is noted that most of these births took place before trilene came into wide use in obstetrics. The efficacy of gas-and-air and gas-and-oxygen appears to be enhanced by the presence of a trained anaesthetist.

The small size of the sample precludes any definite opinion on the relative efficacy of the various drugs and sedatives given in the first stage of labour. The results, however, show considerable dissatisfaction with potassium bromide and chloral mixtures.

Out of a total of 409 mothers who answered the question, "Were you left alone longer than you liked?" 65 answered in the affirmative. Few mothers were made to walk about during their labours when they would have preferred to lie down.

A rather large proportion of the mothers stated that they would have liked more complete relief, 123 out of 425 deliveries, or 29%, for the first stage and 103 out of 425 deliveries or 24%, for the second stage.

The situation with regard to perineal repair appears to be satisfactory.

No information can be obtained from this series regarding the value of antenatal exercises or of preparation for childbirth. Two questions were asked on these points, but no information of practical value could be obtained from the replies.

Dr. K. K. Conrad has carried out a tremendous amount of work in analysing the replies to the questionnaires and in compiling the statistical report. The other members of the subcommittee are greatly indebted to her.

The subcommittee would also like to express its thanks to Miss Mabel Row, secretary of the Medical Women's Federation, for her help with correspondence, in sending out questionnaires, and in tracing names and addresses of medical mothers.

The National Birthday Trust Fund has given this investigation a grant to cover all expenses. The Medical Women's Federation would like to express its great indebtedness to the Fund.

The Ministry of Health has issued a memorandum on the treatment of mentally defective patients from institutions. The foundations of the scheme are (1) the selection of patients fit for community care, (2) choice of a suitable licensee and environment, and (3) social and medical supervision. The fuller the social training given and the greater the degree of supervised freedom and responsibility allowed, the easier it is to judge of a patient's capacity to live outside. An ancillary hostel from which they can go out to daily work is useful in testing their fitness for licence in the community. Mentally defective persons are generally unfit for the responsibility of marriage and parenthood, but the Board of Control considers that, where a patient who has been regarded as sufficiently stabilized for community care is found to be married, the presumption is in favour of discharge provided there is ground for thinking that the couple can maintain a home. Before recalling a patient who marries or is about to marry the superintendent should obtain full information, including a medical report on the patient's mental condition and reports on the character and financial position of the spouse and other relevant circumstances. The Board will then consider this information as well as the opinion of the hospital management committee before deciding on the question of discharge.

TUBERCULOUS MENINGITIS

EARLY DIAGNOSIS, AND A REVIEW OF TREATMENT
WITH STREPTOMYCIN

BY

J. RUBIE, M.D., M.R.C.P.

Assistant Medical Officer, Highgate Hospital
(Archway Group of Hospitals)

AND

A. F. MOHUN, M.B., B.S.

Senior Assistant Pathologist, Archway Group Laboratory

At a unit at Highgate Hospital, established under the auspices of the Medical Research Council, 67 cases of tuberculous meningitis were admitted during the period July, 1947, to August, 1948. We have analysed the clinical and pathological findings in these cases and in a further 9 patients who recovered without streptomycin.

For the purpose of assessing the results of streptomycin treatment the analysis is confined to 54 cases (Table I) admitted during the period July, 1947, to May, 1948, giving a minimum observation period of 231 days (8 months).^{*} Of these cases 23 were included in the Medical Research Council Report (1948).

Diagnosis

History of Contact.—A history of contact was established in 23 of 67 cases (34%). Patients under 3 years of age differed from older patients as shown in Table II.

TABLE II

	Total No.	No. giving History of Contact
Parents under 3 years of age	21	12 (57%)
Patients over 3 " "	46	11 (24%)
	67	23 (34%)

 χ^2 5.7 $P < 0.02$.

Three of the nine patients who recovered without streptomycin treatment gave a history of contact with tuberculosis.

Clinical Findings

Table III summarizes the main clinical findings and illustrates the interval between the first appearance of signs and symptoms and the day of diagnosis—the latter being the day on which the decision was made to start streptomycin treatment.

In this series of 67 cases the basic pattern of the disease was remarkably constant. Tuberculous meningitis has a prodromal period, characterized by irritability, listlessness, and fatigue, and failure to gain (or actual loss of) weight. It is not possible to know how long this stage lasts in any given case; it may be a few days or as long as three months. The child may appear to recover temporarily, or may pass directly into the next stage, characterized by headache, vomiting, anorexia, constipation, and fever (in that order of frequency of occurrence). Table III shows that diagnosis was most commonly made eight to fifteen days after the beginning of this second stage. Drowsiness, squint, photophobia, and neck rigidity came later, preceding diagnosis by one to five days.

Twenty-one of our patients were under 3 years of age. In this age group some of the signs and symptoms described above are not easily discernible or are impossible to elicit because such patients are often unable to convey complaints.

^{*}Cases admitted after May, 1948, form part of a series alternate members of which received intrathecal "sulphetrone" in addition to streptomycin; we hope to report on this series later.

TABLE III.—The Interval between the First Appearance of Signs and Symptoms and the Day of Diagnosis

		Days before Diagnosis									
		0-3	4-7	8-11	12-15	16-20	21-30	31-40	41-50	51-60	61-70
Headache	..	2	3	12	10	2	6	1	0	1	1
Vomiting	..	4	10	16	5	2	4	0	0	0	0
Anorexia	..	1	2	5	7	3	3	2	0	0	0
Constipation	..	0	5	5	3	0	0	2	0	0	0
Irritability	..	2	2	4	4	2	1	2	1	0	0
Fatigue	..	0	3	2	2	3	1	1	1	0	0
Wasting	..	0	0	0	2	1	1	0	1	1	0
Drowsiness	..	6	8	6	3	1	0	0	0	0	1
Squint	..	3	1	0	0	0	0	0	0	0	0
Fever	..	1	2	6	3	1	2	0	0	0	0
Neck rigidity	..	21	7	2	0	0	0	0	0	0	0
Paralysis	..	0	0	1	1	0	0	0	0	0	0
Fits	..	4	0	1	0	0	1	0	0	0	0
Delirium	..	1	2	0	0	0	0	0	0	0	0
Coma	..	6	0	0	0	0	0	0	0	0	0
Abdominal pain	..	0	1	0	1	0	0	0	0	0	0
Diarrhoea	..	0	1	0	2	0	0	0	0	0	0
Photophobia	..	4	0	0	0	0	0	0	0	0	0

The figures in the body of the table indicate the frequencies of occurrence of the intervals.

The prodromal features may be missed in this group; listlessness may be difficult to detect, and minor degrees of irritability may be attributed to teething or feeding difficulties. Such patients may be unable to disclose the presence of headache (the earliest and the commonest ever in the next stage), so that vomiting becomes the presenting feature. In very young patients the disease tends to run a more rapid course; the vomiting may rapidly give place to meningism, squint, drowsiness, and soon to coma. Vomiting (rapidly followed by meningism) was the earliest sign in 23 of the 67 patients, and 16 of these 23 were not more than 3 years of age, the oldest of the 23 being years of age.

Apart from the variations in mode of onset due to age certain less common signs and symptoms may be superimposed on the general pattern, or the presenting feature may be notably few in number. Three patients (all under 3 years of age) presented with fever only—followed by neck rigidity within a few days. In three cases diarrhoea accompanied vomiting, giving rise to a misleading picture of gastro-enteritis; in another two cases abdominal pain was prominent. Fits or convulsions occurred in six patients in one of these the fits preceded all else by ten uneventful days; in another the fit was followed by a hemiplegia which lasted six hours and then disappeared; in the remaining four patients fits were a late feature.

Transient paralysis of arm and leg (lasting 24 hours) occurred in one case 15 days before diagnosis and led to an initial diagnosis of poliomyelitis. Transient loss of speech for a few hours accompanied by a headache (which persisted) was noted in one case 40 days before diagnosis. Symptoms of the "middle stage" (see below) followed two weeks later. In two cases whooping-cough, and in one case mumps, occurred a few weeks before the onset of signs and symptoms of tuberculous meningitis.

In three cases the child had sustained a blow on the head before the illness. One of these cases was admitted to a hospital with headache and vomiting following a kick on the head, and was there found to be suffering from tuberculous meningitis (previously the child had appeared to be quite well).

On admission to the unit, all cases were classified in the following manner. Early cases (E): fully conscious patients with no focal signs and little or no meningism, but with pathological cerebrospinal fluid and a characteristic meningeal picture. Middle cases (M): fully conscious but sometimes drowsy and lethargic, with neck rigidity and perhaps focal signs. Advanced cases (A): unconscious or deeply stuporous patients. The length of the period of illness before admission bore no constant relation to the stage on admission.

Mental Picture on Admission.—The mental picture was that of apathy, with poverty of speech and movement even in fully conscious patients—often accompanied by resentment of even the slightest interference. We have come to the conclusion that this mental attitude is the most valuable single criterion in the differential diagnosis from other forms of meningitis. The apathy may later give place to a state of confusion, in which the patient lies quietly in bed; interrogation will reveal varying degrees of withdrawal from the environment. Occasionally noisy confused behaviour alternates with the apathy. This mental picture is of course recognized as indicative of raised intracranial pressure.

Eyes.—Papilloedema is a common finding in middle or advanced cases. Choroidal tubercles were seen in 5 cases in association with miliary tuberculosis of the lungs accompanying the tuberculous meningitis.

Diagnostic Investigations

(i) **Mantoux Test.**—This was completed in 51 cases; 16 patients lived only a few days after admission. The reactions are shown in Table IV.

TABLE IV

	E Cases	M Cases	A Cases	Total Cases
Positive at 1 in 10,000 ..	17	13	4	34
" " 1 in 1,000 ..	6	3	3	12
" " 1 in 100 ..	0	3	1	4
Negative in all three dilutions ..	0	1	0	1

A positive reaction was defined as an area of oedema measuring at least 8 mm. in diameter.

(ii) **Chest Radiograph.**—Definite abnormalities in the chest x-ray film were seen in 50 of 66 cases (one patient died before radiographs could be taken). They comprised:
a) A primary complex (usually hilar adenitis, sometimes accompanied by indications of pulmonary collapse) in 35 cases. *(b) Miliary disease of the lungs* in 13 cases. (A further 6 cases proved at necropsy to have miliary disease of the lungs, although there was no radiological evidence of this during life.) *(c) Phthisis*, present in two adults. In the remaining 16 cases no abnormality was seen.

(iii) **Cerebrospinal Fluid.**—The following investigations were carried out:

Cell Count.—The cell count ranged between 30 and 1,000 cells per c.mm. The figure bore no relation to the stage of the disease on admission. The picture was predominantly lymphocytic in all but two cases.

Protein Content.—All cases (with one exception) showed increased protein at the initial lumbar puncture: the figures ranged from 35 mg. to 3.5 g. per 100 ml., and bore no relation to the stage of the disease, except that grossly raised protein levels were usually associated with spinal loculation due to spread of the disease down the theca.

Chlorides.—It is generally appreciated that though a falling chloride level in the C.S.F. is often found the level is not usually of great help in diagnosis, because in early cases it may be quite normal or only slightly reduced. Our figures confirm this view.

Sugar.—C.S.F. sugar levels were not accurately estimated in the early period of our work, as it was not appreciated that diagnostic information would be obtained. When later such estimations were performed approximately 1 ml. of C.S.F. was collected in a separate bijou bottle containing an appropriate amount of sodium fluoride. The sugar levels at initial lumbar puncture are summarized in Table V. It will be seen that in no case was the level above 45 mg. per 100 ml. The significance of these figures is discussed later.

Direct Examination of C.S.F. for Acid-fast Bacilli.—Prior to and within 48 hours of admission, acid-fast bacilli were seen in the centrifuged deposit of the C.S.F. in 39 of 67 cases (58%).

TABLE V

C.S.F. Sugar mg./100 ml.	No. of Cases	C.S.F. Sugar mg./100 ml.	No. of Cases
5+	2	30+	1
10+	4	35+	5
15+	6	40+	2
20+	4	45+	—
25+	4	50—	—

Five further cases first showed acid-fast bacilli at later dates. The organisms were often very scanty in number.

Culture and Guinea-pig Inoculation.—Culture of the C.S.F. was made on Löwenstein medium in every case and a guinea-pig inoculation was carried out. The results* are summarized as follows: total cases, 67; positive by culture and/or guinea-pig, 58 (87%). Nineteen cases whose C.S.F. was negative by direct examination for acid-fast bacilli were verified bacteriologically by culture and/or guinea-pig inoculation. Four cases were diagnosed by microscopical examination of the C.S.F. but failed to yield positive cultures or inoculations. (The diagnosis in these cases was verified at necropsy.) If these are added to the positive cultures and inoculations the total number of cases diagnosed bacteriologically (otherwise than by post-mortem examination) is 62 (92%). Varying numbers of strains from 43 patients have shown no significant streptomycin resistance.

Differential Diagnosis

Nine patients admitted to the unit as cases of tuberculous meningitis were not treated with streptomycin. Meningitis was present in all. Their ages and the findings in the C.S.F. are given in Table VI.

TABLE VI

Case No.	Age (Years)	C.S.F. Findings				Remarks
		Cells	Protein	Chlorides	Sugar	
68	4½	193 (L. 95%)	160	710	—	N. in 19 days
69	8½	Blood-stained fluid with excess W.B.C.	35	740	—	N. " 9 "
70	6	570 (L. 65%)	20	740	—	N. " 20 "
71	1½	56 (L. 100%)	20	740	50	N. " 14 "
72	1½	60 (L. 95%)	20	750	—	N. " 7 "
73	4½	34 (L. 80%)	40	695	—	N. " 3 "
74	8½	95 (L. 15%) P. 85%	60	700	60	N. " 9 "
75	½	18 (L. 100%)	20	760	—	N. " 10 "
76	½	85 (L. 25%) P. 75%	35	705	67	N. " 23 "

N. = Normal. L. = Lymphocytes. P. = Polymorphs.

Case 68.—Mantoux-negative. Chest radiograph, negative. History of contact, negative. Meningism, slight. No focal signs. Mentally alert. The meningism disappeared within 48 hours of admission. C.S.F. normal in 19 days; subsequent history uneventful.

Case 69.—Mantoux-negative. Chest radiograph, negative. No history of contact. The infant was unable to sit up, but seemed mentally alert. Full recovery with normal C.S.F. in 9 days.

Case 70.—Mantoux-negative. Chest radiograph, negative. History of contact, positive. Meningism slight. No focal signs. Patient mentally alert. Meningism disappeared within 48 hours of admission.

Case 71.—Mantoux-negative. Chest radiograph, negative. History of contact, positive. Definite meningism, with right sixth nerve paralysis. Patient mentally alert. This case caused us considerable anxiety at the time of admission. The picture was suggestive—but the mental condition (and the high sugar content in the C.S.F.) led us to withhold treatment. The child was much better within 48 hours—all meningism disappeared and the patient stood up at the foot of the cot and played happily. The C.S.F. was normal in 14 days. Subsequent history uneventful. Very slight right sixth nerve weakness persists.

In the four above cases a diagnosis was never established. It is possible that they were cases of polio-encephalitis. It is also possible that Case 71 was in fact an abortive case

*These results do not allow comparison to be made between Löwenstein culture and guinea-pig inoculation, as the number of specimens cultured is greater than the number inoculated into guinea-pigs.

TABLE I.—Details of the 54 Cases dealt with in Section on Treatment

TABLE I. Details of the 54 Cases dealt with in Section on Treatment

52	1 4/12	6	A	O	O	O	P.C.	+	3	I.M.	Admitted hopelessly ill	
53	2 6/12	9	A	+	+	+	P.C. Mil.* P.C.	+	3	I.T. + I.M.	Admitted hopelessly ill	
54	2 1/12	10	A	O	+	O	O	O	2	I.T. + I.M.	Admitted hopelessly ill	

E = Early case. M = Middle case. A = Advanced case. P.C. = Primary complex. Mil. = Military disease of lungs. Mil.* = Military found P.M.
 I.T. + I.M. = Intrathecal + intramuscular. I.M. = Intramuscular. I.M.→I.T. = Intramuscular going on to intrathecal.

Charts of the 54 cases detailed in Table I

of tuberculous meningitis, although this seems unlikely. We favour the diagnosis of polio-encephalitis here too.

Case 72.—This patient was in hospital following a pleural effusion, and was awaiting transfer to a pleural-effusion unit is a case of primary tuberculosis. Mantoux-positive. He developed a fever accompanied by headache and vomiting. The C.S.F. was pathological (see Table VI), but this child in particular was alert and happy. The C.S.F. was normal in 7 days.

Case 73.—After two months' history of listlessness, anorexia, and abdominal pain this patient had a fit and was admitted to a hospital in an unconscious state. He recovered consciousness but was mentally unstable: a week later he had a series of fits, after which his reflexes were absent and his plantar responses extensor. At this time the Mantoux reaction was very strongly positive at 1 in 10,000. He was transferred to our unit with the provisional diagnosis of tuberculoma of the brain. He had no further fits. His C.S.F. became normal in 3 days, and clinically he recovered completely. We had the advantage of seeing him late in the illness, when he was recovering and was mentally and clinically normal.

Case 74.—This patient was in a sanatorium for treatment of a large primary complex. His chest radiograph showed right hilar adenitis with pneumonic changes in the upper lobe. He

had displayed meningism. On admission to the unit he was mentally alert, and showed some slight neck rigidity but no focal signs. The C.S.F. became normal in 9 days.

Case 75.—This child had pulmonary tuberculosis with a pleural effusion. She became febrile again, vomited, and was less playful. Neck rigidity and drowsiness were noted. She was admitted with a C.S.F. picture as shown in Table VI. Clinical examination on admission (11 days after the onset of these symptoms) was negative. Her C.S.F. became normal in 10 days.

Case 76.—A boy aged 5½ years was admitted from a sanatorium where he had been under observation for primary tuberculosis of the right lung with a pleural effusion. He complained of headache and was febrile. Table VI shows the C.S.F. findings at the initial lumbar puncture at the sanatorium. He was admitted to the unit, and 48 hours after the initial lumbar puncture the C.S.F. showed: W.B.C., 316 per c.mm. (lymphocytes 100%); protein, 25 mg. per 100 ml.; chlorides, 725 mg. per 100 ml.; sugar, 37 mg. per 100 ml. In spite of this suggestive finding he was mentally alert, and he had no meningism or focal signs. The C.S.F. the next day showed: W.B.C., 184 per c.mm. (lymphocytes 100%); protein, 25 mg.; chlorides, 710 mg.; sugar, 55 mg. He remained well, was not treated with streptomycin, and the C.S.F. became normal in 23 days.

Cases 72-76, it will be noted, showed evidence of existing tuberculous infection, with a positive Mantoux reaction or an abnormal chest radiograph. (In this respect they differ from the first four cases described above.) It seems possible that they were examples of serous tuberculous meningitis (Lincoln, 1947).

In cases of miliary disease of the lungs receiving intramuscular streptomycin we have observed transient meningeal reactions, lasting 7-10 days and characterized by C.S.F. pleocytosis, raised protein, but normal sugar.

It is difficult to give precise reasons for the decision not to begin treatment with streptomycin in the nine cases summarized above: undoubtedly the mental condition of the patients was a factor. The contrast between this comparative alertness and the apathetic detachment of cases of tuberculous meningitis is an extremely useful guide to diagnosis. Perhaps a mother's statement that her child is "not himself" is in reality the earliest possible detection of this sign. Professor Craig (1948) stresses the early stage of this withdrawal from contact with others and gives a very full account of the subtle mental changes often noticed first by the mother.

In regard to the findings in the C.S.F., these are incomplete in respect of sugar estimations, as six of the above nine cases were admitted before our realization that such estimations might be valuable. In Cases 71 and 74 the C.S.F. sugar content was a factor in the decision not to treat with streptomycin. We agree with Lincoln (1947) that the low sugar content may be the earliest informative change in the C.S.F. in tuberculous meningitis, but it may not be evident when other symptoms are already suggestive, as the following case shows.

Case 18.—This is a proved case of tuberculous meningitis and is now doing well under treatment. The disease started with a convulsion. C.S.F. examination showed no abnormality: W.B.C., 4 per c.mm.; protein, 15 mg. per 100 ml.; sugar, 82 mg. per 100 ml.; chlorides, 770 mg. per 100 ml. Eight days later the C.S.F. showed: W.B.C., 500 per c.mm., mainly lymphocytes; protein, 60 mg.; chlorides, 730 mg. The child had suffered from erythema nodosum five months previously; chest radiographs showed a well-marked primary focus. She was admitted to the unit, and the C.S.F. findings were: W.B.C., 603 per c.mm., mainly lymphocytes; protein, 140 mg.; sugar, 40 mg.; chlorides, 690 mg. Three days later the findings were: W.B.C., 193 per c.mm.; protein, 160 mg.; sugar, 22 mg.; chlorides, 700 mg. Acid-fast bacilli were seen.

This case shows that in the earliest stages the C.S.F. may be normal. This point was also illustrated in Case 9, in which a normal C.S.F. was found at initial lumbar puncture and in which the C.S.F. became abnormal five days after the onset of symptoms. Case 36 showed a normal C.S.F. 11 days after the first symptoms. The first pathological C.S.F. was found 15 days after the onset of symptoms.

The causes of a lymphocytic cell increase in the C.S.F. may be summarized as follows: (1) Tuberculous meningitis, and serous tuberculous meningitis; (2) polio-encephalitis and poliomyelitis; (3) benign lymphocytic choriomeningitis; (4) glandular fever (infectious mononucleosis); (5) mumps encephalitis; (6) spirochaetal infections (syphilis, leptospiral diseases, relapsing fever); (7) infective hepatitis; (8) atypical pneumonia; (9) herpes zoster; (10) psittacosis; (11) trypanosomiasis; (12) yeast meningitis.

Summary and Conclusions in Regard to Diagnosis

Chest radiography, lumbar puncture, and the injection of 0.1 ml. of 1 in 1,000* Mantoux reagent should all be

*Omission of the 1 in 10,000 dilution is considered justifiable: 48 hours may be saved, and the risk of troublesome local reaction is small.

performed within 48 hours and not be spread over several days.

We had hoped to be able to discover at least one diagnostically helpful feature in the C.S.F. But it is now clear that such a hope did not take into account the urgent necessity for earlier diagnosis. It is true that *when the disease has reached the stage indicated in the cases reviewed in this report* the most useful findings in the C.S.F. (if acid-fast bacilli are very scanty or absent) are the low sugar content, the raised protein, and the increased (lymphocytic) cell count—in that order of importance.

There is a high correlation between the speed of diagnosis and success in treatment.

Reference to the nine cases reviewed under "Differential Diagnosis" shows that patients may present themselves with a history of contact with tuberculosis, with evidence of extrameningeal tuberculosis, and with abnormal C.S.F. and yet may not develop what is ordinarily regarded as tuberculous meningitis. Our experience suggests that the crucial feature in diagnosis is the clinical picture—in particular the mental state of the patient. By this criterion we have (apparently successfully) distinguished the cases referred to above.

Lincoln (1947) and Choremis and Vrachnos (1948) have described cases displaying acid-fast bacilli in the C.S.F. but not developing tuberculous meningitis. On the other hand, three of our cases (9, 18, and 36) which in spite of suggestive clinical features initially showed a normal C.S.F. subsequently developed typical tuberculous meningitis.

Review of Treatment with Streptomycin

The scheme of streptomycin treatment we follow is: intrathecal and intramuscular, 28 days; intramuscular, 28 days; intrathecal and intramuscular, 28 days; rest period, 28 days; intramuscular only, 28 days. The intramuscular dose is 0.02 g. per lb. (0.45 kg.) body weight in 24 hours, given six-hourly. The intrathecal dose is 0.1 g. in 10 ml. normal saline daily. Further treatment is given subsequently if indicated.

On this scheme we have cultured tubercle bacilli from the C.S.F. in cases (which have since recovered) as follows: in 3 cases, 21 days after the beginning of treatment; in 1 case 53 days after; in 1 case 56 days after.

We feel, therefore, that there is no case for lessening the intensity or duration of the initial attack and are inclined to favour the suggestion of Dubois *et al.* (1947) and the practice of Smith, Vollum, and Cairns (1948) that *45 days or more initial intrathecal therapy should be given.* This is, however, difficult because of the chemical meningitis and the general ordeal of treatment. One or two days' rest during intrathecal treatment allows the chemical meningitis to abate.

It is possible to effect a cure with intramuscular streptomycin, but we agree with the conclusions reported by the Medical Research Council (1948) that combined therapy gives better results, though there may be a misleading initial response.

During streptomycin treatment patients show to a varying degree fever, loss of weight, anorexia, vomiting, and skin rashes. With the exception of the last-named, these features if severe and prolonged, are due to the disease rather than the drug. Chemical meningitis varies in intensity. The urticarial rashes respond to "benadryl" and those of the exfoliative dermatitis type to local application of cod-liver oil. Towards the end of the intrathecal course patients complain of severe pains in the legs, probably due to nerve-root irritation. A soft growth of hair on the body

(chiefly back, limbs, and neck) is common. Eyelashes become very long; scalp hair often falls out.

Most of the signs and symptoms seen before and during treatment are due to increased intracranial pressure, at first probably a diffuse swelling of the brain, but sooner or later hydrocephalus. Vascular lesions cause paralysis and occasionally death, and the exudate may be responsible for cranial-nerve abnormalities, especially of the third, sixth, and seventh nerves.

Drowsiness, voracious appetite (somewhat resembling the Kleine-Levin syndrome), facial flushing, glycosuria, hyperthermia, hyperalgesia, and emotional instability may be due to the hydrocephalus and its effect upon the midbrain, thalamic, and hypothalamic regions; or, on the other hand, the dominant lesion may be a tuberculous arteritis depriving these centres of their blood supply (Smith, Vollum, and Cairns, 1948).

We consider that carpo-pedal spasm and main d'accoucheur, resembling tetany, are manifestations of tonic fits (Ford, 1946). They do not respond to calcium.

C.S.F. during Treatment

Intrathecal, but not intramuscular, streptomycin causes a pleocytosis. A steadily rising protein level is usually of bad omen, indicating an extension of disease down the spinal theca. We have, however, seen complete recovery after the lumbar C.S.F. protein had reached 11 g. per 100 ml. Table VII shows the streptomycin levels in a case on

TABLE VII

Time	Streptomycin Content (Micrograms per ml.)	
	Lumbar C.S.F.	Cisternal C.S.F.
12 noon. Before treatment (0.1 g. streptomycin given intrathecally by lumbar route)	0	0
1 p.m. " " " " " "	4,400	174
4 p.m. " " " " " "	1,000	—
12 midnight " " " " " "	40	—
12 noon (24 hours after injection) " "	10	3.3

intrathecal therapy. Tests on another patient (24 hours after lumbar injection of 0.1 g.) showed a ventricular level of 2.7 micrograms per ml.

Return to Normal.—So long as intrathecal streptomycin is continued the C.S.F. remains abnormal in cell content. It gradually becomes more normal when streptomycin is stopped, and in the absence of relapse complete return to normal has been noted at approximately 200 days from the beginning of treatment on the lines described. However, cases have been observed in which, in spite of apparent clinical recovery, the C.S.F. cell count remained slightly raised. A further month's course of streptomycin was given to these cases, but the abnormality persisted and the C.S.F. did not return to normal till seven months after the cessation of all treatment and approximately a year after admission. Of the 18 cases which have survived for more than 230 days, 14 have a normal C.S.F. No case in which the C.S.F. has become normal has relapsed.

Chest Lesions.—Streptomycin does not seem to affect the process of healing of the tuberculous adenitis which accompanies the primary infection. Miliary tuberculosis of the lungs, however, clears radiologically in from 8 to 12 weeks. Such clearance occurred in one case in which nevertheless death resulted from tuberculous meningitis.

Eighth-nerve Lesions.—Audiogram tests were carried out in 8 cases. One child (Case 1) is very deaf and slightly ataxic; it is difficult to decide whether this is due to the streptomycin or to the disease. We believe it is due to the tuberculous meningitis. Audiograms on the other children

showed a loss of hearing of 10–20 decibels at all frequencies, but it requires this special test to detect the abnormality. A second child (Case 2) is very slightly ataxic, but the disability is improving rapidly and is hardly discernible. An older case (No. 12) was ataxic—in particular in the dark of the cinema; but with special exercises at King's College Hospital he too has improved.

Surgical Intervention

Ten cases have been operated on with the object of relieving hydrocephalus. The operations tried included the placing of a plastic tube 1 mm. in diameter in the lateral ventricle through a burr-hole. The hydrocephalus is of the communicating type, and, whereas in chronic hydrocephalus this operation is disappointing, in this acute condition (especially as the cause has been shown by Sir Hugh Cairns and others to be pressure of the brain back against the free margin of the tentorium) we felt it should be tried. We hoped that by relieving the intracranial tension we could break the vicious circle by relaxing the brain away from the tentorium and at the same time allow the drug to circulate. The approach is either by the anterior or by the posterior route.

A child aged 1½ years (admitted later than May, 1948) was treated by intrathecal and intramuscular streptomycin for a month, but a week after intrathecal therapy was stopped he vomited and cried and developed increasing meningism. A plastic tube was inserted into the right lateral ventricle through a frontal burr-hole and left *in situ* for six weeks. A Bateman needle occluded the end, and the stylet was removed every six hours to allow the C.S.F. to drain. (The lumbar C.S.F. protein rises while this is being done.) The tube has now been out for four months and the child appears to be responding. It seems that this operation relieved the acute hydrocephalus. This child is the only survivor of the 10 cases surgically treated.

In another infant Mr. Dickson Wright placed a fine tube into the third ventricle and ran the other end over the cortex backwards. In this case the child was too ill for the operation to have a chance.

A girl of 15 relapsed after seven months—a situation in which we have found that the mere placing of a tube into the lateral ventricle does no good. Mr. Dickson Wright raised a frontal flap, and in addition to the ventricular tube a second tube was placed at the site of the disease, in front of the optic chiasma, and streptomycin was given through it. She improved and life was certainly prolonged, but ultimately she died. Necropsy showed an extensive tuberculous exudate at the base of the brain.

To summarize, while surgical intervention seems to offer a logical approach to the relief of the hydrocephalus, our results have been disappointing. Only one of the ten cases thus treated survives, but in other cases life was certainly prolonged. Operation is useless in advanced cases. The difficulty is to formulate the indications for surgical intervention, which will probably need to be early to be successful. Further work on this problem is essential.

Other Factors in Treatment.—Many of these cases were admitted to the unit in a dehydrated condition, but it is remarkable how even the most drowsy will take fluid by mouth in automatic fashion. If this is not possible then rectal or intravenous fluid should be given. Chloral and barbiturates are used when indicated for restlessness or insomnia.

Nursing

The nursing of the cases presents a special problem. The patients are often irritable, unreasonable, and confused. They may be incontinent and wasted, and may vomit frequently. They sometimes refuse food, or are too ill to eat and have to be fed. By pushing food and fluid the

nursing staff can do much to improve the general condition of the patients, which otherwise becomes very poor. Bedsores develop easily, and very special attention must be given to the way in which a semiconscious or drowsy child lies. The constant crying out and the cephalic cry can be very disturbing. We attach importance to the frequent change of posture of these patients and feel that they should be sat up as soon as possible. If this is impossible they should be nursed prone for periods—with the object of preventing the exudate from settling heavily on the under surface of the cerebellum and round the foramina. Young infants who lie supine show this localization of exudate markedly, and it may yet be another factor in the bad prognosis of infants under 3 years of age.

It is our practice to give patients massage and passive exercises after eight weeks and to get them up after three months. Close co-operation with the physiotherapists will prevent much pain and delay in ultimately walking again.

In this unit we do all the lumbar punctures on a high narrow table, not in the bed. No local analgesic is used. Very difficult cases are premedicated with tab. "seconal," in dose according to age. The skin is sterilized with ether, spirit, and iodine; and thin, sharp lumbar-puncture needles are used (Howard Jones type). The latter are of various lengths from 2-3 in. (5-7.5 cm.), and are sterilized in packets in the autoclave in the operating theatre. After adequate scrubbing-up by the operator the punctures are performed without touching the shaft of the needle. No collodion or dressing is applied, but the skin is moved to break the track. A minimum of trauma and the avoidance of "bloody taps" are extremely important, especially in young infants. Patients need to be kept in hospital for five to six months and should then go to a suitable convalescent home for six months, but should still have cerebrospinal fluid examinations, probably fortnightly, for control.

Mention must be made of the problems which arise in regard to the relatives of the patients. These people are under great emotional stress, and this persists for several months in a way not commonly met with in other circumstances. The greatest tact and understanding are required from the nursing staff and others in dealing with these unfortunate people.

Results of Treatment

Table I details the cases admitted before May 28, 1948 minimum observation period of surviving cases, 231 days). We hesitate to regard any case as certainly cured. Our longest-surviving case has been under observation for 560 days (18 months). The 36 patients who died include 9 who lived for seven days or less after admission. Of the 8 surviving cases 14 have a normal C.S.F. (Cases 1, 2, 3, 5, 6, 7, 8, 9, 10, 12, 14, 16, and 18). All have been bacteriologically proved except Case 16. The remaining 4 survivors show the following features:

Case 15.—Clinically recovered. C.S.F. normal except for low sugar. (Further observation is required to estimate the significance of delayed return to normal of the sugar level.)

Case 13.—Clinically recovered. C.S.F. shows slight pleocytosis and slightly increased protein.

Case 11.—This case has relapsed twice, and, although there was apparent response to further treatment, has a C.S.F. which is abnormal in respect of protein (55 mg. per 100 ml.).

Case 17.—Has relapsed once. Otherwise resembles Case 11.

When clinical suspicion of relapse is aroused a fall in the C.S.F. sugar should be regarded as confirmation.

The poor prognosis in patients under 3 years of age is largely due to the rapidity with which they reach the advanced state of the disease, as is shown in Table VIII.

TABLE VIII.—Cases under 3 Years

Stage on Admission	No.	Survivors
Early	3	0
Middle	4	1
Advanced	10	0
Total	17	1

Table IX summarizes the results with reference to stage on admission, and distinguishes the 40 cases which had the standard course* of treatment from the remainder (admitted in the earlier part of our work before the superiority of "combined" treatment was established).

TABLE IX

Course of Treatment	Stage	Cases	No. Surviving
Intramuscular only	E	2	2
	M	4	0
	A	4	0
Total		10	2
Intramuscular, followed by intrathecal	E	2	0
	M	2	1

Combined I.T. and I.M. course (with minor variations shown in Table I)	E	14	8 (57%)
	M	16	6 (37%)
	A	10	1 (10%)
Total		40	15 (37%)
Overall totals		54	18 (33%)

These results emphasize the importance of the earliest possible diagnosis of tuberculous meningitis. Apart from streptomycin, the most important single factor in such success as we have had is to be found in the quality of the nursing. At Highgate Hospital Sister S. E. Robinson and the nursing staff have maintained the highest standard in this respect.

Summary

Diagnosis

The clinical and laboratory findings in 76 admissions are analysed. A diagnosis of tuberculous meningitis was made in 67 cases. The remaining 9 included five examples of a meningeal reaction in tuberculous subjects which may have been cases of serous tuberculous meningitis.

The problems of early diagnosis are discussed in relation to these cases. Mental apathy is an important early diagnostic feature. In 3 cases of tuberculous meningitis the C.S.F. was normal in the earliest stage in spite of clinically suggestive features. Diagnostically important C.S.F. changes are fall in sugar, rise in protein, and pleocytosis.

Prior to and within 48 hours of admission acid-fast bacilli were seen in the C.S.F. in 39 cases (58%). *M. tuberculosis* was recovered by culture and/or guinea-pig inoculation in 58 cases (87%). Diagnosis by one or both of these criteria was established in 62 cases (92%).

A positive history of contact with tuberculosis was obtained in 12 of 21 patients (57%) under 3 years of age, and in 11 of 46 patients (24%) over 3 years of age.

The commonest interval between the first appearance of signs or symptoms and the day of diagnosis was 8-15 days.

The Mantoux reaction was positive in 50 of 51 cases.

Abnormalities in the chest radiograph were seen in 50 of 66 cases.

Treatment

Cases were classified on admission as "early," "middle," or "advanced." Of these, 54 are considered, with a minimum observation period of 231 days (8 months). Forty cases received combined intrathecal and intramuscular streptomycin: of these, 15 (37%) survive—comprising 8 of 14 early cases

*With minor variations shown in Table I.

(57%), 6 of 16 middle cases (37%), and 1 of 10 advanced cases (10%).

Ten cases received intramuscular therapy only (in the early part of our work), and two survive. Four cases received intramuscular therapy followed by combined therapy: one of these survives.

Important factors operating against success are vascular changes in the brain and hydrocephalus. Further work is essential to assess the value of surgical intervention to combat the hydrocephalus.

Strains of *M. tuberculosis* isolated from 43 patients have not shown resistance to streptomycin.

Eighteen cases (33%) survive, and of these 16 show full clinical recovery—14 having entirely normal C.S.F. and 2 showing slight abnormalities. Two survivors have a history of relapse and show definitely abnormal C.S.F. The diagnosis has been confirmed bacteriologically in all except one of the survivors.

Apart from streptomycin, the most important aids to successful treatment are the rapidity of diagnosis and the quality of the nursing.

The value of intrathecal sulphathione in addition to streptomycin is now being investigated.

We wish to thank the following for advice and help: Dr J. M. Alston, pathologist, Archway Group Laboratory (who also kindly performed the streptomycin-sensitivity tests); Dr A. B. Bratton and staff of the Central Histological Laboratory; the numerous technicians who helped, especially Mr. Hurst, of the Archway Group Laboratory, who gave much care and time to the pathological side of the work; Mr. J. V. Broad, otorhinologist; Dr C. D. Coyle, medical superintendent, Archway Group of Hospitals; Dr M. Daniels and Dr P. D'Arcy Hart, of the Medical Research Council; Mr. A. Dickson Wright, consulting neurosurgeon; Mr. G. Dorling, surgeon, Archway Group of Hospitals; Mr. G. Ebbage, ophthalmologist; Dr A. L. Jacobs, physician, St. Mary Islington Hospital; Dr S. Oram, physician, King's College Hospital, London, in co-operation with whom Case 12 was treated; Dr H. E. S. Pearson, physician Highgate Hospital; and Dr F. L. Rayner, radiologist.

NASAL CARRIERS AND STREPTOCOCCAL TONSILLITIS

BY

G. T. COOK, M.D.

Bacteriologist, Public Health Laboratory Oxford

AND

D. MUNRO-ASHMAN M.B., B.S., C.P.H.

School Medical Officer

In discussing the possible sources of streptococcal infection in puerperal fever Colebrook (1933) considered that the nasal carrier might prove of greater danger than the throat carrier. Hamburger (1944), in a study of the transmission of streptococcal infection in Army hospital wards, showed that the incidence of cross-infections did not necessarily show a close correlation with the throat-carrier rate and suggested that some carriers were more likely to spread infection than others. Further studies by Hamburger and his associates demonstrated not only that many more streptococci were expelled into the environment by nasal carriers than by throat carriers (Hamburger *et al.*, 1945a), but also that the majority of hospital cross-infections studied could

be traced to heavy nasal carriers (Hamburger *et al.*, 1945b). Their findings led to an investigation of the relative importance of nose-blowing, sneezing, and coughing by nasal carriers in the dissemination of streptococci; it was shown that blowing the nose expelled the largest numbers of organisms and also resulted in sudden and heavy contamination of the hands (Hamburger and Green, 1946). These workers concluded that in certain situations, such as hospital wards, Army barracks, and boarding-schools, nasal carriers were of more importance in the spread of streptococcal disease than throat carriers because they caused a greater degree of environmental contamination. In such communities secondary reservoirs of infection—e.g., dust and bedding—are probably of special significance, and the part played by dormitories in the spread of scarlet fever, diphtheria, and streptococcal tonsillitis has been demonstrated (Dudley, 1923, 1926; Hamburger *et al.*, 1945b).

The outbreak of tonsillitis to be described illustrates the importance of both the nasal streptococcal carrier and the dormitory in the spread of infection in a residential school over a period of two terms. Symptoms were mild, complications few, and there were no rashes. Recovery was rapid and boys were usually discharged from the sanatorium in five to seven days.

The Outbreak

The school of 340 boys is housed in five separate buildings, which will be referred to as houses A-E. Each house has its own sleeping accommodation and common-rooms. D house has its own dining-room, but the boys from all other houses feed in the dining-room of A house, though each house has its own table. The classrooms are in a separate building and are shared by all the boys. Thirty-two of the 57 cases occurred in A house, where the sleeping accommodation consists of six dormitories holding 48 boys and 85 single rooms, the latter chiefly occupied by older boys. The boys of this house, whether sleeping in dormitories or in single rooms, mix freely with each other in the common-room and to some extent with the members of B, C, and E houses at meal-times. All boys meet other members of the school during classes, games, chapel, etc.

Epidemiology

The first case, H., occurred in A house on Feb. 16, 1948, and was admitted to the sanatorium with a sore throat and fever. A throat swab examined by another laboratory showed the presence of haemolytic streptococci, but these were not typed at that time, though later swabs grew haemolytic streptococci type 12. This boy returned to the school on Feb. 26; two days later a fresh case was reported, and further cases continued to occur almost daily till the end of the term on March 25. Cases of streptococcal tonsillitis due to the epidemic type were again observed within a few days of the beginning of the summer term, and 20 further cases among the boys occurred during this term, eight of them within the first two weeks. The last of these became ill on July 3. The accompanying Chart shows the daily incidence of cases of tonsillitis among dormitory and single-room boys of A house and the rest of the school. The overall pattern suggested an initial spread through A house, boys in dormitories especially being attacked, with a gradual extension to other houses towards the end of the Easter term. This general spread was continued during the following term until all houses had at least one case.

In all, 57 boys were attacked with acute tonsillitis—37 in the Easter and 20 in the summer term. Of the 37 cases in the first term 29 were in A house. The incidence of disease among boys in A house and the rest of the school for each term is shown in the Table, A house being divided

Table showing Incidence of Cases among Boys in A House (Dormitories and Single Rooms) and in Rest of School during Easter and Summer Terms

House	No. at Risk	No. Attacked		
		Easter Term	Summer Term	Total
A (dormitory)	48	19 (39.5%)	2 (4.2%)	21
A (single rooms)	85	10 (11.8%)	1 (1.1%)	11
B, C, D, E	207	8 (3.9%)	17 (8.2%)	25
Total	340	37 (10.9%)	20 (5.8%)	57

into those boys sleeping in dormitories and those in single rooms. During the Easter term the attack rate for boys in A house sleeping in single rooms, while higher than that for the rest of the school, was considerably lower than the attack rate for the dormitory boys. This difference is statistically significant; the probability of its occurring by chance is less than one in a thousand. The attack rate for each of the six dormitories in A house varied from 0 to 73%, though the numbers upon which these results are based are small.

In addition to the 57 boys, five members of the staff had tonsillitis—two in A house during the Easter term and three in other houses the following term.

Field and Laboratory Investigations

The aid of the laboratory was sought in the early days of the epidemic, when the majority of cases were from the dormitories of A house. It was therefore decided to take nose and throat swabs from all cases still in the sanatorium and from boys sleeping in the dormitories of A house. This was done on March 12, and further swabbing of new cases and carriers was repeated at intervals till the end of the term.

Grouping and typing were carried out the first time haemolytic streptococci were isolated from the nose or throat of any boy and on all subsequent isolations, except when the interval between swabbings was only a few days.

1 strains were typed at the laboratory by Griffith's slide agglutination technique and reacted with sera of types 5 and 12. The type was confirmed as type 12 by Lancefield's precipitin method in a number of strains examined from cases and carriers.

Streptococcus pyogenes, type 12, was isolated from 43 out of 57 boys either during their illness or, in some of the earlier cases, after their return to school. Most of the cases with negative swabs were undergoing local chemotherapy at the time the swabs were taken. The epidemic strain was isolated from the five members of the staff who became ill. It was also readily obtained from the dust of two dormitories and two day-rooms in house A during the Easter term and from the dust of one of these dormitories towards the end of the Easter holidays.

Preventive Measures

These were directed towards reducing the dust content of the school buildings and sterilizing the noses of persistent carriers. Thorough suction-cleansing and scrubbing of the premises were carried out during the Easter holidays

together with oiling of dormitory and common-room floors in A house. During the summer term all known nasal carriers and some throat carriers were each treated with penicillin-sulphathiazole snuff and penicillin throat sprays four times a day for fourteen days. The boys continued with their usual school activities during this time. The results of treatment are discussed later.

The Association of Nasal Carriers with New Cases

During the time the first case (H.) was in the sanatorium no further cases of tonsillitis developed in the school, but two days after his return to school a second boy became ill, followed by another six in the next three days. When H. was first swabbed fifteen days after his return from the sanatorium he was found to be a heavy nasal carrier, and it is reasonable to assume that he had been carrying streptococci in large numbers in his nose since his release.

A study of the distribution of 19 cases and four contact carriers among the six dormitories showed

that 18 of these occurred in three dormitories with a total population of 28 boys and only five in the other three dormitories housing 20 boys. The attack rates for these two groups were 64 and 25% respectively. The first case in each of the three dormitories comprising the first group was found to be a heavy nasal carrier (at the time of the general swabbing of boys in the dormitories) and at least one heavy nasal carrier was present in each dormitory during the time streptococcal infections were occurring. Nasal carriers were not found in any of the three dormitories of the group with the low attack rate, except in one dormitory for the last four days of the term.

Throughout the summer term only three nasal carriers from the previous term were detected; a fourth carrier was later identified when a boy with a nasal discharge was swabbed. Only one of these boys slept in a dormitory (one of those heavily infected the previous term), and all four carried for a short time only and responded well to a course of local chemotherapy. During this term the incidence of tonsillitis throughout the school was lower than during the previous term and no dormitory outbreaks occurred.

Persistence of the Carrier State

The work of Lemon and Hamburger (1946) has suggested that most symptomless nasal carriers are missed cases and that true contact carriers are unusual. No mass swabbing of the school was carried out, and it was not possible to form any estimate of the probable carrier rate, though six out of 33 dormitory contacts were carrying streptococci in the nose or throat on the occasion of the swabbing of all dormitory boys on March 12. Two of these developed tonsillitis three days later.

Type 12 streptococci were isolated from 35 boys during their illness—in 13 cases from the nose and usually from the throat, and in 22 from the throat only. Twenty-three of the 35 boys were swabbed ten days later; streptococci were obtained from the nose of three out of eight boys

Chart showing daily incidence of new cases of tonsillitis among boys for the Easter and summer terms.

previously carrying in the nose, and from the throat of 11 out of 15 boys carrying only in the throat.

Twenty-five boys were carrying type 12 streptococci in the nose or throat when last swabbed at the end of the Easter term. Twenty-one were re-swabbed six weeks later at the beginning of the following term and 12 were still carriers of the epidemic type—three in the nose and throat and nine in the throat only. The three nasal carriers and five of the throat carriers were each treated for fourteen days with penicillin-sulphathiazole snuff and penicillin throat sprays and all 12 carriers were re-swabbed at the end of the term. All the nasal swabs were then negative, though two of the eight treated boys and three of the four untreated boys were still carrying in the throat.

One boy had a clinical attack of tonsillitis in both the Easter and the summer term, and type 12 streptococci were isolated from the throat on each occasion. This boy was not one of those swabbed at the beginning of the summer term, so it is not known whether he was a throat carrier from the previous term. This experience is unusual and contrary to previous reports. The second attack was less severe than the first and streptococci were isolated in small numbers only, so it is possible that this illness was not primarily a streptococcal infection. The serum of this boy was not examined for anti-streptolysin titres.

Presence of M Substance

Typing by the precipitin technique was attempted on 10 strains isolated from throat carriers at the end of the summer term and seven gave a positive reaction. This was particularly well marked in strains from three boys who had been carrying for at least 130 days; strains from four new cases in the summer term gave either weak or negative results. These findings are of particular interest in view of the degradation or progressive loss of M substance during the carrier state found by Rothbard and Watson (1948). In this outbreak typing by the precipitin technique was done on only a small number of strains, but a greater proportion of weak or negative results were obtained with strains isolated from boys infected at the end of the epidemic than with those from the earlier cases. The clinical symptoms were also less severe in the later cases.

Discussion

The pattern of the daily incidence of new infections (see Chart) suggests that the epidemic spread fairly rapidly through A house during the three weeks after the return of H., a heavy nasal carrier. By the end of the Easter term it had extended to boys in other houses, and it continued in the rest of the school the following term. During the first 18 days after the return of H. 17 new cases occurred among the boys in dormitories and nine among those in single rooms, the number at risk being 47 and 85 respectively. Thirteen of the 17 dormitory cases occurred in three dormitories where 27 boys were at risk. It is clear that during this time boys in dormitories suffered more heavily than the others and that most of the cases came from three of the six dormitories.

Glover (1920) has drawn attention to the importance of overcrowding in sleeping-quarters as a factor in the production of high carrier rates in cerebrospinal fever. The relation of dormitories to the spread of scarlet fever and diphtheria in naval training establishments was later shown by Dudley (1923, 1926). It is possible that the closer contact of the dormitory boys, together with their younger age, was partly responsible for their high attack rate compared with those boys sleeping in single rooms. On the other hand, not all those dormitories were heavily attacked (in one dormitory no case occurred), although the spacing of

beds, general ventilation, and ages of the boys in each were similar.

It is significant that during the eighteen days when most of the cases in A house occurred nasal carriers were associated with each of the three dormitories most heavily attacked and were not detected in the others. The first case in each of these dormitories was subsequently identified as a nasal carrier, and it was only after this boy's return to the dormitory that other cases occurred. In fact, a heavy nasal carrier was present in each of these dormitories during the time all except one of the boys became ill. One or more boys were carrying large numbers of streptococci in the nose for at least sixteen days in each of these three dormitories, and it is likely that a heavy streptococcal contamination of the environment took place during this time.

Streptococci of the epidemic type were readily isolated from the dust before the majority of dormitory infections had occurred. In addition to the possibility of infection being transmitted more or less direct from the carrier, the dormitory population was thus also exposed to the further risk of a heavily infected environment for several hours each night. Considerable dispersal of streptococci into the air and on to exposed clothing from floor dust and bedding would take place when the boys entered the dormitory at night and again during bed-making in the morning, and the attack rate under these conditions is likely to be high. The beds of the cases were not necessarily adjacent or in close proximity to the bed of the carrier, and the scattered spatial distribution of cases in the dormitories suggested general contamination of the environment. A study of the streptococcal content of the air and environment in wards and barracks occupied by streptococcal carriers has shown that the dispersal of organisms is commonly widespread and not limited to the vicinity of the beds occupied by carriers (Lemon, Loosli, and Hamburger, 1948). In this outbreak neither the streptococcal content of bedclothes or air nor the ability of the nasal carriers to infect their environment was investigated.

Out of 57 cases, however, only 15 came from the three dormitories heavily attacked during the Easter term. The remaining 42 were either boys sleeping in single rooms or sporadic cases in different dormitories. It seems evident, therefore, that a heavily infected dormitory environment was not the chief mechanism by which infection was conveyed to most of the school. Type 12 streptococci were recovered from the dust of the common-rooms in A house during the Easter term, and no doubt other infected environments played a part in spreading disease. All recognized nasal carriers were successfully treated in school during the summer term, but 12 fresh cases occurred during and after their period of treatment before the outbreak ceased. No swabbing of contacts was done during this term, and it is possible that an undetected carrier was responsible for the continuance of cases. Other factors concerned with the spreading of disease may have been infected dust in classrooms, the breathing of air infected by nose-blowing or the use of handkerchiefs, or the transmission of organisms from clothing or hands, either direct or from inanimate objects (Brown and Allison, 1937; Hamburger and Green, 1946; Dumbell *et al.*, 1948; Duguid and Wallace, 1948).

Epidemics of streptococcal tonsillitis in boarding-schools usually run on in the form of "dropping" cases to the end of the term (M.R.C., 1938), and this outbreak proved no exception. The occurrence of streptococcal infections of the same type in successive terms is not unusual, and Boissard and Fry (1944) attributed cases of scarlet fever in the autumn term and the following summer term to the same heavy nasal carrier. This boy was away for the intervening term, during which no

Experience of this and other epidemics has shown the frequent association of heavy nasal carriers with outbreaks of streptococcal tonsillitis in residential schools. It is important that nasal as well as throat swabs should be obtained from all cases, however mild; heavy nasal carriers should be treated until their swabs are negative. This is especially necessary with the single case or in the early stages of an outbreak before widespread contamination of the environment and the build-up of a carrier rate has occurred. During the holidays every effort should be made to sterilize the noses of persistent carriers and to disinfect school premises.

Summary

The epidemiological and bacteriological findings in an outbreak of streptococcal tonsillitis in a residential school are described. The outbreak extended over two terms, and 57 out of 340 boys were attacked.

All the early cases were in the same house as the first case, a heavy nasal carrier. A nasal carrier was also associated with each of the three dormitories with the highest attack rates during the time fresh infections were occurring. In most cases, however, the dormitory did not appear to be of special importance in the spread of disease, and the significance of this is discussed.

The early detection and isolation of heavy nasal carriers before widespread dispersal of infection has occurred is emphasized.

SPONTANEOUS PERFORATION OF THE OESOPHAGUS

SURGICAL REPAIR, WITH RECOVERY

BY

JOHN SCHOLEFIELD, F.R.C.S.

Surgeon, West Middlesex Hospital, Isleworth

This rare condition has been the subject of a number of papers, chiefly dealing with single case reports. It is probable that it is not so uncommon as is supposed. Thus Eliason and Welty (1946) were able to record three cases seen by the senior author in the space of twelve months. The mortality until recently has been 100%, but Barrett (1947) and Olsen and Clagett (1947) have recorded recoveries after immediate operative intervention and repair.

In view of these successes it seemed timely to review the condition once more and to put on record two further cases, the second of which represents the third recovery that can be found in the literature; for, as Eliason and Welty (1946) say, "with improved techniques in anaesthesia, freer use of blood and plasma and effective chemotherapeutic agents, the limiting factor in the treatment of this condition is that of diagnosis."

Case 1

A man aged 41 was admitted to the West Middlesex Hospital at 4.30 a.m. on Dec. 10, 1941, with a diagnosis of perforated gastric ulcer. He had always enjoyed good health, apart from occasional indigestion, till 8.30 p.m. the previous day, when after a bout of vomiting he was stricken with severe pain in the lower chest and lumbar regions. A large midday meal of sausage pie was the only explanation the patient could give for the initial vomiting. There was no history of alcoholism. The pain, which was intense, had become more widespread; it was especially felt in the scapular regions and was made worse on breathing. His only other complaints were severe dyspnoea and an inability to lie flat in bed. The temperature was 101.2° F. (38.4° C.), pulse 100, and respirations 64. The blood pressure was 130/100.

Examination on admission revealed a cyanosed, breathless man of rather stout build. His breathing was shallow and obviously painful. At this time no abnormal physical signs were found in the lungs or cardiovascular system. His tongue was moist. The abdomen was tense and rigid but not tender. Rectal examination was negative. The diagnosis was thought to rest between a coronary thrombosis, lobar pneumonia, diaphragmatic pleurisy, and a ruptured oesophagus.

Morphine, $\frac{1}{2}$ gr. (16 mg.), was given and the patient placed in an oxygen tent. A radiograph of the chest taken four hours later revealed a bilateral pleural effusion, but further detail was obscured by respiratory movement, the patient being unable to hold his breath. By this time, some twelve hours after the onset of the catastrophe, the effusions were quite obvious clinically, and well-marked surgical emphysema had begun to develop in both supraclavicular triangles and was extending on to the chest wall. A confident diagnosis of spontaneous rupture of the oesophagus was made. The patient's condition, however, rapidly deteriorated and he died at 6 p.m. on the day of admission—i.e., about 22 hours after the onset of his illness. Before death the surgical emphysema had involved the whole of the upper half of the body and had closed both eyes. It was noted at the time how little relief this patient obtained from repeated doses of morphine.

Necropsy revealed a linear rupture 1 in. (2.5 cm.) long on the anterior aspect of the oesophagus $3\frac{1}{2}$ in. (8.75 cm.) from the cardia. A large quantity of fluid was present in the posterior mediastinum, and 24 oz. (680 ml.) of blood-stained turbid fluid was found in the right pleural cavity and 18 oz. (510 ml.) in the left. No direct communication could be demonstrated between the mediastinum and pleural cavities. Apart from the tear the oesophagus had no disease of any kind, and the rest of the necropsy was essentially negative.

Case 2

A woman aged 63 was admitted to the West Middlesex Hospital on Dec. 1, 1947, with a diagnosis of ? perforated peptic ulcer. After a heavy meal of tinned meat, cheese, and milk at 8 p.m. the previous day she had vomited twice, and this was rapidly followed by agonizing pain starting in the region of the upper part of the sternum and rapidly spreading to the epigastrium. The pain, which was severe and constant, was made worse by breathing and movement. There was no history of previous indigestion or alcoholism.

Examination revealed a pale, dyspnoeic, rather stout woman in extreme shock. The temperature was 100.8° F. (38.2° C.), pulse rate 124, and respirations 32. The blood pressure was 85/60. The trachea was centrally placed; there were rales at the left base and dullness at the right base. Surgical emphysema was present over the upper sternum. The heart appeared normal. There was rigidity of the whole anterior abdominal wall, with pronounced tenderness in the epigastrium. Normal peristaltic sounds were audible and rectal examination was negative.

She was seen by Dr. J. A. Torrens, who suggested the diagnosis of ruptured oesophagus, and exploratory thoracotomy was advised in spite of the patient being *in extremis*.

It was decided to explore the right chest in view of the effusion on this side, and accordingly a large segment of the eighth right rib was resected and an excellent exposure obtained by means of rib-spreaders. At least 2 pints (1.14 litres) of

fluid resembling weak tea was evacuated from the right pleural cavity and a small rent in the mediastinal pleura demonstrated. This was widely opened and much blackish foreign material was removed from the posterior mediastinum. Fragments of food were identified, and one was impressed by the large quantity of undigested food present.

A small vertical linear tear 1 in. (2.5 cm.) in length was found on the right posterior wall just above the diaphragmatic orifice. This was rapidly closed with interrupted fine catgut sutures, and the posterior mediastinum and pleural cavity were cleansed so far as was possible. A soft corrugated rubber drain was inserted across the pleural cavity into the posterior mediastinum, and the chest wall was closed around this and a large tube to the pleural cavity. Penicillin, 500,000 units, was injected into the pleural cavity at the close of the operation and closed drainage instituted. Shock was treated by plasma. fluid requirements were met by intravenous glucose-saline, and infection was controlled by systemic penicillin and sulphamezathine. A radiograph two days later showed that the right lung had re-expanded, though there was now a little fluid in the left pleural cavity.

The mediastinal drain was removed and daily intrapleural injections of penicillin were continued. The intravenous drip was removed on the fourth day and a milk drip by means of a Ryle's tube substituted. At this time the left pleural cavity was aspirated and some 7 oz. (200 ml.) of straw-coloured fluid were obtained. The tube in the pleural cavity was shortened and finally removed on the twenty-first day after operation. The Ryle's tube was removed on the fourteenth day; but some leakage of milk occurred across the pleural cavity, so the tube was replaced. Two further trial removals were made, with further leakage, but eventually the Ryle's tube was discarded on Jan. 22, 1948, some eight weeks after operation. No further leakage occurred and normal diet was rapidly resumed. Excellent nutrition was maintained throughout by these means.

The patient was discharged on Feb. 18 with the wound almost healed, and when seen ten days later complete healing had taken place. Repeated chest films during the post-operative period had revealed a gradual return to normal, and a barium swallow on Feb. 26 showed an oesophagus of excellent calibre with slight dilatation of the lower end to the right, presumably due to adhesions. A letter from the patient at the end of June, 1948, told of perfect health and an ability to eat anything.

Incidence, Aetiology, and Clinical Course

Since the first classic case described by Boerhaave in 1724, Olsen and Claggett (1947) have been able to find some 60 cases in the world's literature. The majority of these were first diagnosed at necropsy, and only 14 were diagnosed before death. It should be made clear that these cases are those in which spontaneous perforation of a normal oesophagus has taken place, and that perforation of an oesophageal peptic ulcer or other disease process and rupture following instrumentation are excluded. The former inevitably fatal outcome allowed ample necropsy evidence that the oesophageal wall was indeed normal. There is no evidence to show that the muscle wall in these cases is exceptionally thin, and any congenital weakness can also be ruled out by the late onset of this catastrophe.

The presenting feature in almost all recorded cases is that of vomiting, and the sequence of events is probably as follows. The patient, after some dietetic indiscretion or a particularly heavy meal, begins to retch or vomit. There is a rapid rise in intragastric pressure, which is transmitted to the oesophagus. The sphincter at the cricoid level fails to relax and the oesophagus tears at its weakest point—that is, at the lower end of the oesophagus just above the diaphragm. Such tears have been produced experimentally and have also occurred in patients following crushing injuries to the abdomen, during convulsions, and after defaecation.

Barrett (1946), in a most comprehensive survey of the whole subject, has stressed the high percentage of alcoholics among these patients, and it is thought that, though alcohol

may have a deleterious effect on the oesophagus, it is the vomiting and retching it produces which is the important factor. However, as he points out, this condition is unfortunately not confined to gluttons and alcoholics.

The pathological findings are remarkably constant. A linear longitudinal tear 1–8 cm. in length, usually on the left posterior wall, is most often present, and this involves the lower end of the oesophagus just above the diaphragmatic opening. The right posterior wall, as in Case 2 above, may be affected, and occasionally two tears have been present. It will be noted that the tear was on the anterior wall in Case 1. The posterior mediastinum becomes filled with food and regurgitated gastric contents, and the pleural cavities may be secondarily involved.

Males are predominantly affected, and Ridgway and Duncan (1937) were able to find only five females in the 35 cases recorded at that time. The middle-aged are most often affected, and my second case is the oldest of those recently reported.

As noted above, vomiting and retching usually initiate the process. This is rapidly followed by pain, variously located in the upper abdomen, the lower part of the sternum, or posteriorly on the left at the level of the lower thoracic or upper lumbar vertebrae. The pain is severe and agonizing, and has sometimes been described as tearing in character. A feature noted by several authors is the lack of relief obtained from morphine. The patient shows the usual features of shock, the pulse being rapid and the temperature subnormal, though the latter may be raised. Dyspnoea, pain on breathing, and cyanosis are commonly present, and the respiratory rate is increased. The patient is unable to lie down, some relief being obtained by sitting up in bed.

In the very early stages there may be tenderness and guarding, amounting to board-like rigidity in the epigastrium, and many of these cases have come to laparotomy on the erroneous diagnosis of a perforated peptic ulcer. Very shortly two phenomena develop which give the surest clues to the diagnosis. First, unilateral or bilateral pleural effusion appears. Initially this is probably reactionary to the highly irritating gastric contents in the posterior mediastinum, but soon gastric juice itself appears in the pleural cavity, either because the tear involves the pleura or because it bursts through the pleura, and may readily be recognized on aspiration and analysis. Secondly, in many cases surgical emphysema has developed; this begins over the upper part of the sternum and then spreads to the neck and face.

Should all the classical features be present, diagnosis should not be difficult provided the condition be known to the clinician.

The chief conditions for which spontaneous perforation of the oesophagus has in the past been confused are perforated peptic ulcer, dissecting aneurysm of the aorta, coronary disease, acute pancreatitis, acute cholecystitis, and spontaneous pneumothorax. A brief consideration of the main symptoms and physical signs should lead to a correct diagnosis in the typical case.

In untreated cases death rapidly occurs, the majority dying within 48 hours. In a few cases the process has been much slower, and at least three such cases have ultimately survived. The mortality in the past for the acute cases which form the vast proportion has been 100%. However, Graham (1944) and Frink (1947) have reported cases of late drainage in patients who appear to have localized the spreading infection, with ultimate cure.

Barrett (1947) and Olsen and Claggett (1947) have reported successful repair in the early stages, and Case 2 above is a further instance. In all three cases direct approach to

DIAGNOSIS OF VIRUS DISEASES

Diagnostic Procedures for Virus and Rickettsial Diseases. By various authors. (Pp. 347; illustrated. \$4.00.) New York: American Public Health Association, 1790, Broadway. 1948.

Virus diseases can be diagnosed and studied in the laboratory; many of them are of such importance that in the future the appropriate techniques will have to be available in many hospital and public health laboratories and not only in research institutes. This book is a mine of information, for its 17 chapters are all written by specialists, who tell how much can be done and is being done in the U.S.A. The specialists have been "given their head" to describe how they deal with the viruses which are their own special study, and no attempt is made to insist that exactly similar methods are described where one technique is applicable to several viruses. Some duplication is thus inevitable.

Some of the authors have interpreted their instructions liberally. Thus, the article by Meyer and Eddie on psittacosis, and some of the others, give much interesting assorted information about the virus concerned. On the other hand, the chapter by Parker on variola and vaccinia is almost too concise. That on poliomyelitis by J. R. Paul is full of useful information on the caging and handling of experimental monkeys. Phlebotomus (sand-fly) fever seems rather out of place in such a book, for human volunteers are necessary for any experimental study. Trachoma, influenza, mumps, rabies, yellow fever, and rickettsial diseases are among the other more important subjects discussed. Workers in diagnostic and in research laboratories will have many occasions to seek—and find—in this book the facts they need.

C. H. ANDREWS.

INFERTILITY

The Childless Marriage. Its Cause and Cure. By Edward F. Griffith, M.R.C.S., L.R.C.P. (Pp. 206; illustrated. 8s. 6d.) London: Methuen and Company. 1948.

Sterility and Impaired Fertility. Pathogenesis, Investigation, and Treatment. By Cedric Lane-Roberts, C.V.O., M.S., F.R.C.S., F.R.C.O.G., Albert Sharman, M.D., Ph.D., M.R.C.O.G., Kenneth Walker, M.A., M.B., B.C., F.R.C.S., F.I.C.S., B. P. Wiesner, D.Sc., Ph.D., F.R.S.Ed., and Mary Barton, M.B., B.S. Second edition. (Pp. 400; 96 figures; 2 plates. £1 4s.) London: Hamish Hamilton Medical Books. 1948.

Both these works were first published in 1939, and their second editions represent extensive revision made necessary by the many advances in knowledge and alterations in outlook which have occurred in the last decade. Dr. Griffith's book is not strictly a second edition, for it first appeared under a different title—*The Childless Family*. It is intended for the lay reader, is compact and cheaply produced, but contains a lot of information—perhaps too much. Many of the more strictly medical points, which the author advises the lay reader to skip, could be omitted. Although there are few, if any, errors in fact, outlook is not always scientific, and some of the statements might be misleading to anyone without medical knowledge. The association between abortion and seminal faults is overstated to the extent that it might cause unjustifiable alarm, and the account of continence in the male leading to sluggishness of spermatozoa could have unfortunate repercussions. The recitation of individual cases is not convincing, nor are the illustrations of hystero-graphs, some of which are alleged to demonstrate uterine hypoplasia. Is it possible, at any rate without a specially controlled technique, to recognize this condition by this means? Nevertheless the book has much to commend it, and any couple who read and understand it will be left with a relatively wide knowledge of infertility, its causes, how it should be investigated and by whom, and the prospects for its cure. The final chapter, which occupies 40 pages, comprises a very full account of artificial insemination, setting out the arguments for and against, and giving many useful references. This alone justifies a place for the book in the general practitioner's library.

Sterility and Impaired Fertility is written on a different plane and prescribes for the general practitioner and consultant. It is one of the best books of its kind and already has a high reputation. The new edition has the same format as its predecessor, although the text is considerably modified in places. Dr. Mary Barton has now joined the team of authors and makes her presence felt by a new emphasis on cervical function and sperm penetration of cervical mucus. Other changes include a simplification in the technique and interpretation of semen analysis, the rejection of hormone analysis as a practical measure of real value, and a more cautious outlook on the value of hormone therapy and on the interpretation of tubal patency tests. Among some useful appendices may be mentioned a description of a new modification of the method of estimating pregnanediol in the urine, and a short account of irradiation of the pituitary and the ovary by Dr. Anthony Green. It is rather surprising to find that the carbohydrate in semen is still referred to as glucose when most workers now consider it to be mainly fructose. Moreover, there appears to be no mention of precoital douches of either sodium bicarbonate or glucose as a method of treatment. Although this may be regarded as old-fashioned and empirical it is widely used and at least deserves discussion. These, however, are small matters when considered in the perspective of this otherwise wide and authoritative account of fertility and infertility, an account which deserves to continue to be looked upon as a standard work for reference.

T. N. A. JEFFCOATE.

PUBLIC HEALTH IN THE U.S.A.

Public Health Administration in the United States. By Wilson G. Smillie, A.B., M.D., Dr.P.H., Sc.D. Third edition. (Pp. 637; illustrated. \$6.50 or £1 12s. 6d.) New York and London: The Macmillan Company. 1947.

The title of this book might suggest a discourse on the details of administration of public health in the United States with fairly ample reference to public health law, but this is not the author's line of approach. He discusses many diverse problems in hygiene. In a short first part he outlines the scope of public health functions; Part II is entitled "Administrative Control of Communicable Diseases," Part III "Basic Activities of a Health Organization," and Part IV "Organization of Public Health Programs."

The student of medicine will appreciate the section on infectious diseases, where the author describes not only the action taken by a health department in respect of various diseases but also their epidemiology, clinical features, and differential diagnosis. The reader is thus led to realize that sound administrative action must be based on the clinical and epidemiological features of a disease. The author makes a plea that there should be no rigidity of action in dealing with cases of infectious disease. He expresses the accepted modern view that infectious-diseases hospitals should be part of a general hospital scheme, since to-day their chief value is the advantage the patient derives from skilled treatment rather than the protection of the public by his isolation. As is to be expected, the discussion on epidemiology is especially directed to American problems, such as the differing incidence and manifestations of diseases in white and coloured peoples. He considers at length such diseases as malaria and rabies, whereas he makes little mention of bovine tuberculosis; his account of the work of port health departments, especially in relation to the spread of infectious disease, is not satisfactory.

The author lays great emphasis on the work of the public-health nurse. He discusses the ways in which her services may be utilized by a health department and whether each nurse should be limited to a special branch of public health nursing. Throughout the book he draws attention to the duty of health departments to educate the public, and he points out that in this respect there are virgin fields to be explored. Public-health departments in Britain may find this subject of particular interest now that they are being relieved of some of their former functions. The sick individual, in his view, is not the responsibility of the health department, and he emphasizes the value of "well child conferences." The author maintains that, ideally, prenatal service should not be a function of the health

department, since the medical supervision of the mother during pregnancy should be given by the physician who will have charge of the delivery. However, he realizes that this ideal cannot always be attained, and in these circumstances he stresses the importance of administrative co-ordination between the responsible authorities. He includes notes on such topical subjects as the rhesus factor, epidemic diarrhoea of the newborn, and fluorine in relation to dental caries. He defines geriatrics as the study of persons over 40 years of age, and indicates the value of periodic health examinations (or health inventories).

The chapters on administration, towards the end of the book, will give European readers a conception of the peculiarities of central and local government in a federation of States. The author uses the discussion on this subject to emphasize many of the more important points raised earlier in the text. Possibly the non-American reader would have benefited from the administrative information being included at the beginning rather than the end of the book. Illustrations are numerous and good, and—what is of considerable importance in this type of book—it has an adequate index and comprehensive lists of references on the wide range of subjects discussed.

R. T. BEVAN.

A SURGEON'S LIFE

The Trent and I Go Wandering By. Stories of over fifty years of my life in Nottingham. By R. G. Hogarth, C.B.E., D.L., J.P., F.R.C.S., Hon.L.D.Ed. Foreword by Lord Webb-Johnson. (Pp. 144. 12s. 6d.) Nottingham: Cooke and Vowles, Ltd., The Thoroton Press, St. James's Street.

The Trent and I should be assured of a welcome in and around Nottingham, for since 1894 there are few local institutions and events and very few prominent citizens with whom Mr. Hogarth has not had professional and apparently inevitably friendly relations. It is a very discursive book, rambling over the life of a successful surgeon and devoted citizen. It fully supports what the author says of himself, "I have enjoyed life." His versatility is amazing, and he seems to have worked as hard at his hobbies as he did at his profession. His medical career has been bound up with the Nottingham General Hospital, which he has seen enlarged and improved almost out of recognition since the days when he was a house-surgeon. His story of how he took the risk of a plunge into consulting surgery from a successful general practice is vividly told, as is the struggle to persuade his hospital to establish a pay-ward. This met with considerable opposition which momentarily disturbed his relations with the management of the hospital.

The older members of our Association remember Mr. Hogarth as its President in 1926 at one of our most successful Annual Meetings. It was a happy thought to include in this volume his memorable presidential address, full of common sense and delivered with immense gusto. His fame as a surgeon was recognized far afield and by good judges such as Lord Moynihan and Lord Webb-Johnson, who contributes an appreciative foreword to the book.

The influence of sport on Mr. Hogarth's career is well brought out—a successful athlete, a more than average cricketer and footballer, an enthusiastic motorist in the early days. Indeed, there is scarcely a branch of sport in which he has not indulged and been proficient. He gives the palm to fishing, especially salmon-fishing. Fishing, he says, "has been my principal joy and pleasure—but I have derived much the same from my work, and what more can a man ask?"

There is an eloquent and sensible chapter on "Importance of Health," with some shrewd reminders of the tendency in democracy to ignore the value of self-discipline, as shown for example in the shocking way in which our streets and parks are desecrated by litter. One notes that he has the usual surgeon's view of the value of "a bottle of medicine"—and he speaks with a knowledge of both sides. I was glad to note once again in the presidential address his quip about "the waters of healing laid on at the main" in Harley and Wimpole Streets. It is a happy book, especially welcome to those who know the author and his wife, to whom both he and Lord Webb-Johnson pay a graceful tribute.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Krebsmetastasen. By H. E. Walther. (Pp. 560. 60 Swiss francs.) Basle: Benno Schwabe. 1948.

A monograph, with many references to the literature, on metastasis of malignant growths.

The Clinical Examination of the Nervous System. By G. H. Monrad-Krohn, M.D., F.R.C.P. 9th ed. (Pp. 459. 16s.) London: H. K. Lewis. 1948.

An introductory manual, with many illustrations and diagrams.

A Shetland Parish Doctor. By H. P. Taylor, J.P., M.B., C.M. (Pp. 136. 10s. 6d.) Lerwick, Shetland: T. and J. Manson. 1948.

The late Dr. Taylor's autobiography, with illustrations from his hand.

The Chemist and Druggist Year Book, 1949. (Pp. 666. No price.) London: Morgan. 1948.

A compendium of information useful to pharmacists.

Vitamins and Hormones. Edited by R. S. Harris and K. V. Thimann. Vol. 5. (Pp. 478. \$7.50.) New York: Academic Press. 1947.

Articles by various authorities on recent advances in knowledge.

Bone Marrow Biopsy. By S. J. Leitner, M.D. English translation revised and edited by C. J. C. Britton, M.D., Ch.B., D.P.H., and E. Neumark, M.B., B.S. (Pp. 433. 42s.) London: J. and A. Churchill. 1949.

An illustrated monograph, with extensive bibliographies.

Abdominal Operations By Rodney Maingot, F.R.C.S. 2nd ed. (Pp. 1,274. 84s.) London: H. K. Lewis. 1948.

A detailed account of technique for the surgeon.

Operative Dental Surgery. By J. B. Parfitt, L.R.C.P., M.R.C.S., F.D.S.R.C.S., and W. E. Herbert, L.R.C.P., M.R.C.S., F.D.S.R.C.S. 6th ed. (Pp. 454. 30s.) London: Edward Arnold. 1948.

A textbook for dental students.

Company Finance for Everyman. By L. Mundy, O.B.E. (Pp. 84. 4s.) Oxford: Pen-in-Hand. 1948.

A simple explanation of how to understand balance sheets.

An Introduction to Cardiology. By Geoffrey Bourne, M.D., F.R.C.P. (Pp. 264. 18s.) London: Edward Arnold. 1949.

An account of the chief aspects of cardiovascular disease for students and practitioners.

Psicoanalisi della Vita Istintiva. By J. Flescher. 2nd ed. (Pp. 439. No price.) Rome: Scienza Moderna. 1948.

A study intended for medical men and educationists.

Principles of Biological Assay. By C. W. Emmens, D.Sc., Ph.D. (Pp. 206. 21s.) London: Chapman and Hall. 1948.

A guide for the research worker or analyst on the planning of tests

Practical Public Health Problems. By Sir William Savage, B.Sc., M.D. 2nd ed. (Pp. 197. 14s.) London: J. and A. Churchill. 1949.

Discussion of such topics as the supervision of water supplies, milk, and other foods, the investigation of enteric outbreaks, and house inspection.

The 1948 Year Book of General Medicine. Edited by P. B. Beeson, M.D., and others. (Pp. 821. 21s.) London: H. K. Lewis. 1948.

Abstracts of recent papers, with editorial comment.

A Short Practice of Surgery. By Hamilton Bailey, F.R.C.S., F.A.C.S., F.I.C.S., F.R.S.Ed., and R. J. McNeill Love, M.S., F.R.C.S., F.A.C.S., F.I.C.S. 8th ed. (Pp. 628. 52s. 6d. for 5 parts, not sold separately.) London: H. K. Lewis. 1948.

This part includes accounts of the rectum, abdominal hernia, and the urogenital system.

Ocular Signs in Slit-Lamp Microscopy. By J. H. Doggart, M.A., M.D., F.R.C.S. (Pp. 112. 21s.) London: H. Kimpton. 1949.

Includes many coloured illustrations.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY FEBRUARY 26 1949

A TRUST FUND

The Representative Meeting in June last year referred to the Council a number of motions on the formation of a medical trade union or some other form of organization for the better protection of the interests of the medical profession. Since then the subject has been raised several times in the correspondence columns of the *Journal*. Behind the demand for a medical trade union is the feeling that if the Association had had trade union powers of applying sanctions and granting benefits it would have been in a stronger position in its conflict with the Government in the first half of last year. The demand is, in effect, an expression of dissatisfaction with the B.M.A.'s limited powers in its conduct of negotiations from 1942 to 1948. Behind this demand there is also desire to put more power into the hands of the profession in any subsequent conflict with the Government over the terms and conditions of service in the N.H.S. The Council of the B.M.A., in response to the request of the Representative Body, set up a committee on the constitutional position of the Association, and its report appears in this week's *Supplement*. The report is a long and closely reasoned document which, based on legal opinions of eminent counsel and the advice of the solicitors of the B.M.A., describes the present constitution of the B.M.A. and its advantages and disadvantages; the legal position of a trade union; the possibilities of converting the Association into some other form of organization; and the question of establishing some other form of organization linked to the B.M.A. in a way that would secure identity of interest. The legal arguments are not easy to follow, especially when it is observed that, like doctors, eminent lawyers see fit to differ. The principal conclusions, however, are that it is not possible to convert the B.M.A. into a medical trade union; that even if this were possible the advantages of trade union status are illusory because medical men are neither workmen nor masters and medicine is not a trade; and, finally, that to provide an effective weapon in future controversy a trust fund should be established under the control of a Medical Guild which, legally separate from the B.M.A., can use it for objects not defined in the Memorandum of Association.

The B.M.A. is registered with the Board of Trade as a "Company not for profit," and is thus enabled to dispense with the commercially tinged description "Limited." In granting the Association this licence the Board of Trade insisted on the inclusion in the Memorandum of Association of the proviso to Clause 3, which sets out the objects for which the B.M.A. was established, and Clause 4, which defines and restricts the manner in which the B.M.A. shall dispose of its income and property. The principal object of the B.M.A. is "to promote the medical and allied sciences and to maintain the honour and interests of the

medical profession." An important part of the interests of the medical profession is finance—the adequate payment of medical men for the work they do, linked as this is with the status and prestige of a learned profession in society. When this interest is threatened the B.M.A. is by its constitution limited in the action it can take, being unable to impose restrictions on, or to grant financial benefit to, members who acting on the advice of the B.M.A. suffer financial loss. It was because of this second disability that the Independence Fund, subscribed to by fewer than 6,000 doctors, was established in the early part of last year. It would seem that the B.M.A. is within its constitutional rights to *advise* but not to *organize* collective opposition, but in an acute conflict the dividing line between advice and organization might be hard to define; and any one person could seek an injunction against the B.M.A. on the grounds that its funds were being used in contravention of its Memorandum, and the Association would have to withdraw from the conflict for so long as the matter was being considered by the courts. But whatever the form of organization which might represent it the medical profession as compared with any other section of the community suffers from one big disability, if it may be so termed—namely, that it cannot strike in the sense of withholding its services from sick persons in need of them. If it did that it would cease to be a profession, and would cease to be worthy of its calling. It is, however, open to the medical profession to resign from an organized service such as the N.H.S. and at the same time to continue to look after the sick. If such a grave decision were taken the problem for the doctor would be one of securing payment for work done, or, rather, receiving financial support until the conflict precipitated by resignation had been resolved. It was to this end that the National Insurance Defence Trust was built up by insurance practitioners under N.H.I. and the Independence Fund established last year. It is to this end that the Council is recommending to the Special Representative Meeting to be held on March 29 that a Fund should be set up under the British Medical Guild.

It should not be necessary to set forth in the columns of this *Journal* the advantages of the constitution of an Association which has a proud record of promoting the medical and allied sciences over the past 117 years, but if it changed its nature and became a medical trade union would it in this way overcome the disadvantages it is at present presumed to suffer from? Under the Trade Union Acts the principal objects of any trade union are statutory objects. These are defined as the regulation of the relations between workmen and masters, or between workmen and workmen, or between masters and masters; in this regulation of relations restrictive conditions can be imposed upon the conduct of any trade or business, and benefits may be provided to members. In the opinion of Counsel medical men are neither masters nor workmen, however employed. Medical practice does not come within the definition of "trade," but could be held to be a "business." The statutory objects of a medical trade union would therefore be (1) the imposition of restrictions on the conduct of the business of its members, and (2) the provision to them of benefits. In taking action to defend its rights in a dispute an ordinary trade union

has some degree of legal immunity under the Trade Disputes Act of 1906. In this Act a trade dispute is defined as one "between employers and workmen, or between workmen and workmen." In the opinion of Counsel a medical practitioner is not a workman in the meaning of the Act, nor is he employed in trade or industry. A medical trade union, therefore, would not have (and does not have) this important legal safeguard provided by the Trade Disputes Act of 1906. The medical profession is also in the difficulty that it has hitherto strongly opposed a "closed shop" policy. Its best instincts and traditions would make it hesitate to use the trade union sanction of expelling a doctor from a medical trade union in order to deprive him or her of opportunity for employment.

As it is registered under the Companies Act the Association cannot transform itself into a trade union. If it were to wind up its affairs it would not be able to transfer its assets to a trade union which might take its place. The B.M.A. might free itself from its present restrictions by surrendering its licence to dispense with the word "Limited" in its title and thus be able to alter its Memorandum. This, however, might not be possible if 15% of the members objected; the Association would still have no immunity from legal proceedings, and power to impose restrictions and provide benefits could not become the principal objects of association. During any dispute any one person could still lay an injunction against the B.M.A. on the alleged grounds that these had become principal objects, and that it was therefore in fact acting as a trade union; the Association would be put out of action until the matter had been settled in the courts.

The Council, having dismissed as unrealistic or impossible the conversion of the B.M.A. into some other form of organization, looked into the question of setting up another and parallel body. It considered, for example, the possibility of establishing a medical trade union, membership of which would be conditional on membership of the B.M.A. and *vice versa*. Such a union might because of his failure to conform to policy expel a member, who would then be in the legally impossible position of being expelled from the B.M.A. for failure to conform with the policy the Association by its constitution would be prevented from enforcing. That being so, and even granted that membership of the trade union would be conditional on membership of the B.M.A. but not *vice versa*, the possibility or probability is that the two bodies would be unequal in numbers of members. This is an additional argument to the other ones brought forward against the proposed value of trade union status. The Council has been up against the difficulty that parallel bodies, like parallel lines, might be expected to meet at infinity. It is therefore recommending to the Representative Body that there shall be established a trust fund known as the British Medical Guild. This would be a legally independent entity lawfully able to organize and not merely advise the profession in the event of a dispute with the Government, and able to distribute financial benefits. The Guild would be controlled by a board of trustees, and this board could be composed of members of the Council of the B.M.A. The proposed British Medical Guild is closely similar to the Independence Fund set up last year. The Guild, in fact, would provide

the B.M.A. with weapons which its present constitution prevents it from using. If the Representative Body decides to adopt the suggestion made, then it will presumably support all efforts to secure contributions to the Fund. The relationship of this Fund to the National Insurance Defence Trust has yet to be examined.

The problem is intricate, and made not less so by the legal complexities which surround it. The position of the doctor in the community is in the last resort determined by the fact that he belongs to a learned profession dedicated to caring for the health of the people. The medical profession is older than parliaments and ministries, and whatever the changes in the organization of its services it has always retained its essential character. It is therefore important that, whatever alterations there might be in the form of professional organization, nothing should be done to impair the status and prestige of medicine and those of its traditions which are other than the passing changes of fashion. Apart from the difficulties and disadvantages of converting the B.M.A. into a medical trade union, such a transformation of a voluntary association of medical men and women might end in altering for the worse the essential nature of a great calling. Nevertheless, in a world in which hard economic facts increasingly obtrude themselves the profession needs an economic weapon as a measure of defence. The British Medical Guild is designed to produce this.

SPREAD OF STREPTOCOCCAL TONSILLITIS

Streptococcal sore throat, when unaccompanied by a rash, is not notifiable, and because of this school outbreaks frequently go unrecorded. But even when outbreaks of scarlet fever or streptococcal tonsillitis have been carefully investigated little or no progress has been made in determining the mode of spread or the best methods of control. Throat-carrier rates among contacts could be high or low; and, if some outbreaks ceased abruptly, most went on with cases cropping up throughout the term despite precautionary measures. It has been shown that the spread of streptococcal infections in wards where patients with burns, scarlet fever, and puerperal sepsis were being nursed was associated with gross contamination of the dust and air by the infecting streptococci, and the success of dust-suppressive measures in controlling secondary streptococcal infection in measles wards testified to the importance of this mode of spread. The next step was to find out how the dust became heavily infected.

Although Gordon¹ had shown in 1932 that convalescent cases of scarlet fever with purulent nasal discharge were most likely to give rise to "return" cases and clinicians had long known that the case or carrier of nasal diphtheria was a dangerous source of diphtheria infection, it was the work of Hamburger and his colleagues²⁻⁶ in Army camps during the late war which demonstrated clearly the importance of the heavy nasal carrier in spreading streptococcal infection. After they had confirmed the finding of earlier

⁶ *Ibid.*, 1948, 82, 72.

⁷ *Mon. Bull. Min. Hlth.*, 1944, 3, 160.

workers that patients with strongly positive throat cultures expel only relatively few organisms during talking or coughing, they showed by various tests—cultures of nose-blows, hands, bed patches, and dust—that the heavy nose carrier, whether or not he has any clinical signs of infection, nearly always profusely contaminates his surroundings, and that in fact he disperses about 80 times more haemolytic streptococci than the corresponding throat carrier. They further showed that nose carriers appeared to be responsible for outbreaks of streptococcal infection in hospitals and barracks and, in one instance, for a large-scale food-borne outbreak.

The question remained whether streptococcal infections spread among civilians, particularly among children in schools and nurseries, in the same way as among troops in training. Various recorded outbreaks have suggested that it is so; for example, Boissard and Fry⁷ reported that cases of scarlet fever occurred in a school in the autumn and summer terms when a boy with severe nasal catarrh was present, but not in the spring term when the boy was absent. In this issue of the *Journal* Drs. G. T. Cook and D. Munro-Ashman provide further evidence of the importance of the nasal carrier in the spread of streptococcal tonsillitis in a residential school. The outbreak began when a boy, subsequently shown to be a heavy nasal carrier, returned to his dormitory about the middle of the spring term after an absence of ten days with sore throat and fever. During the rest of the term 19 cases of illness caused by the epidemic type of organism and 4 contact carriers occurred in six dormitories of the house to which the first boy belonged; 18 of these cases came from three dormitories holding 28 boys in all (an incidence of 64%), and in each of these three dormitories the first case was found to be a heavy nasal carrier. The incidence was 25% in the other three dormitories of the same house and 11.8% in the single rooms, where the boys were older and in less close contact with each other. Although the premises were vacuum-cleaned and scrubbed during the Easter holidays, further cases occurred throughout the school in the summer term and continued even after known nasal carriers were treated successfully with penicillin-sulphathiazole snuff. However, there may have been undetected nose carriers, since no mass swabbing was carried out, and there is no mention of examination or infection of the blankets, often an important reservoir of haemolytic streptococci in an infected environment.

The important lesson from this and similar studies is that nose as well as throat swabs should be taken from all close contacts when search is being made for the source of streptococcal infection. If this swabbing can be done early, when only 2 or 3 cases have been reported, and a heavy nose carrier is identified as a likely focus, his removal and treatment may well prevent further spread. Too often, however, the infection is allowed to drag on for some weeks before action is taken, by which time there may be many carriers and a grossly contaminated environment. Large-scale swabbing, isolation of nose carriers, and a thorough "spring-clean" followed by disinfection of the premises and bedding then become necessary. It may be added that outbreaks of infection do not necessarily follow the discovery of nose carriers or streptococcal contaminated

dust. There are other variables—virulence of the organism, the nature and resistance of the community, and the accessibility of organism to host—which play their part, but the potential danger of the nasal carrier cannot now be denied.

RELIEF OF PAIN IN CHILDBIRTH

The report entitled *Maternity in Great Britain*,¹ on which we commented in a leading article a few weeks ago,² exposed many deficiencies in the maternity service. The Press and politicians find this a topic of constant interest and it is not without reason that women will demand that more attention be given to the problem. The main complaint of the mothers interrogated in this survey, which was made jointly by the Population Investigation Committee and the Royal College of Obstetricians and Gynaecologists, was that no attempt was made to relieve the pains of labour. In the Metropolitan boroughs, for instance, only 5% of the mothers confined at home and 48% of those confined in hospital were given relief. The report on pain in childbirth prepared by a subcommittee of the Medical Women's Federation and published elsewhere in this issue therefore appears at an opportune time. If ever a body of women would insist on adequate analgesia during childbirth it would surely be women doctors at their own confinements. There would also be a natural demand on their part for the best environment, accoucheur, and midwife. Yet when this report is examined some disquieting facts emerge. It must have been disappointing for the committee that only 196 replies were received from 300 medical women. The forceps rate of 27% in first deliveries may be due to the fact that most of the mothers were attended by obstetric specialists. In half of these cases the reason for instrumental delivery could not be stated. The perineum was repaired in 69% of first deliveries (normal and abnormal) and 18 of the mothers did not have an anaesthetic for this. The incidence of episiotomy is not stated, and local anaesthesia was used to repair the perineum on only 16 occasions.

It is surprising that 32% of the primiparae were given no analgesic during the first stage. On the other hand 90% received an anaesthetic during the second stage. Most women suffer the greatest pain towards the end of the first stage, when the os is about four-fifths dilated. It is at this time that analgesic drugs can bring such great relief. It is not clear why the subcommittee included gas and-air as an anaesthetic—a claim never made by Minnitt. A mixture of chloral and potassium bromide was prescribed in 80 labours and was ineffective in 38. The combination known as "mothers' mist" is still widely used in this country: the single dose of bromide is not pharmacologically effective, and the dose of the third ingredient, tincture of opium, is often 7½ minims (0.45 ml.), which is equivalent to ⅙ gr. (4 mg.) of morphine. Is there any justification for prescribing this amount? It would seem better to give 30 gr. (2 g.) of chloral. Pethidine was still on trial when this investigation was being made, and doubtless this is the reason why it was given in only 44 deliveries. Not unexpectedly, a mother who was having her third child found "veganin" useless.

¹ *Maternity in Great Britain*, 1948, Oxford University Press, London.

² *British Medical Journal*, 1948, 2, 948.

This group of women is a privileged section of the community in that the standard of obstetric care they receive is much higher than that available to the majority of expectant mothers. The questionnaire showed that opinion was almost unanimous in favour of pain relief in childbirth. Yet a considerable number (24%) said they would have liked more complete relief, and this despite the fact that many were being attended by obstetric specialists. The reasons for this should be sought. Are obstetricians disinterested in obstetric analgesia? Could more effective drugs have been given? Did the mothers react abnormally? The drugs and analgesic apparatus at present available to doctors and midwives are effective provided they are given at the right time and to women who have been properly trained during pregnancy.

It is now generally agreed that the better the mother is prepared during pregnancy for her confinement the less analgesic drug she will need. There is a tendency to rely overmuch upon the hypodermic needle or the tablet as part of a stereotyped system to relieve the pain of uterine contractions. Sometimes the doctor or midwife forgets that the mother is an individual who should and often wants to take an active part in her own delivery. The search for the ideal analgesic must continue, but further investigation should be made of those methods in which explanation and preparation for childbirth play an important part in antenatal care. Midwives conduct most of the deliveries in this country, and they should be able to instruct expectant mothers in the art of muscle control and relaxation. Pain can be relieved in well-trained mothers with the minimum amounts of drugs.

TUBERCULOUS MENINGITIS

Each successive report on the treatment of tuberculous meningitis with streptomycin gains added value from the length of the follow-up of surviving cases and the more mature judgment made possible by longer experience. In this issue we publish an account by Drs. J. Rubie and A. F. Mohun of a study of tuberculous meningitis and its treatment with streptomycin at Highgate Hospital, one of the centres established for this purpose by the Medical Research Council in July, 1947. Perhaps the strongest impression made by this paper is the necessity for early diagnosis and the skill which may be required in reaching it. Particularly instructive is the series of nine patients from whom treatment was withheld, despite meningism, cerebrospinal-fluid lymphocytosis and increased protein, and, in five cases, a suggestive history and known tuberculous foci elsewhere. All these patients recovered spontaneously from whatever cerebral condition they had. It seems that the surest guide to the experienced observer is the mental state: these patients were for the most part alert and happy, whereas the child with undoubted tuberculous meningitis is even at an early stage listless and apathetic. The Mantoux test may be helpful, in that a negative result is a strong point against the diagnosis: in his series the test was negative in only one of the proved cases. Among cerebrospinal-fluid changes a falling chloride content has now by general consent been ousted from its pre-eminent position as a diagnostic sign by a subnormal sugar content, which makes its appearance earlier and is thus of much greater value. This being so, it should be

generally observed that the collection of part of the specimen in a bottle containing sodium fluoride as a preservative is necessary if dependable information is to be obtained on this vital point.

The general results of streptomycin treatment were such as are now expected—recovery (fortunately complete so far as can be seen in 16 of the 18 patients concerned) in about one-third of all cases. The relation between the stage of the disease at which treatment is begun and its outcome is evident—11 of the successful cases being classified as "early," six as "middle," and only one as "late." The effect of age on prognosis is also clear: all the survivors were between 3 and 17 years old. The bad prognosis in infancy is attributed both to the difficulty of eliciting specific complaints in very small children and to the more rapid progress of the disease. Of three patients over 17 years of age all died, presumably because of extensive disease elsewhere—a much more common finding in the adult with meningitis than in the child. The results of different treatment schedules conform to those on which present recommendations by the Medical Research Council are based. Intramuscular administration alone was found to be inadequate; daily intrathecal injection is also necessary, at least in the first month. The present arduous treatment programme occupies five months, two being given to combined treatment, two to intramuscular injection only, and one, the fourth, being a rest period. It cannot be said that the best way of using streptomycin for this disease has yet been defined with certainty: dosage and duration of treatment are not standardized, and some workers have claimed that intrathecal injection alone is necessary. Perhaps the most hopeful line of advance is the combined use of streptomycin with another chemotherapeutic drug such as a sulphone. Such studies are being pursued in several countries, and Rubie and Mohun are themselves using sulphathione in this way. The results of this modification will be awaited with interest.

THE RISKS OF PREMATURITY

The importance of prematurity in relation to stillbirths and neonatal deaths has once again been stressed in a series of articles by Drillien,^{1,2} who has analysed the records of nearly 8,000 births at the Simpson Memorial Pavilion, Edinburgh, during the years 1943 to 1945. Complications of pregnancy, especially hydramnios and antepartum haemorrhage, were found to increase the prematurity rate, stillbirth rate, and neonatal death rate. With a spontaneous vertex delivery the combined foetal and neonatal mortality for premature infants was 21 times greater than for mature infants. Breech delivery increased the risk of death for both premature and mature infants, while the application of low forceps appeared to increase the risk for mature babies only. The principal causes of death in premature babies were prematurity alone, asphyxia, and infections, while in mature babies congenital defects accounted for the majority of deaths. The risk of death from all causes was far greater for the premature than for the mature infant. No diagnosis of a pathological condition was made in over half the stillbirths, but the principal ascertained causes were congenital defects and asphyxia, the former being responsible for more deaths

⁵ *J. soc. med.*, 1947, 67, 409.

⁶ Baird, D., *J. Obstet. Gynaec. Brit. Emp.*, 1945, 52, 217, 339.

in the premature and the latter for more deaths in the mature infants.

By carefully considering the records of each stillbirth and neonatal death Drillien attempted to assess the primary cause in each case. She concluded that congenital defects and erythroblastosis were responsible for nearly 24% of all stillbirths and neonatal deaths, toxæmia and antepartum hæmorrhages for 30%, hazards of delivery for 20%, while all other causes accounted for only 6%. In 20% of the cases the cause was unknown. The investigation was completed by a follow-up of 103 premature and 174 mature infants. There was a significant difference between the ages at which premature and mature infants reached the various "milestones," and the average weight at any given age was found to rise steadily with increasing birth weight. In this follow-up no allowance was made for the degree of prematurity or for social conditions. Drillien points out that authors^{3,4} who have taken the degree of prematurity into account and who have compared the development of premature infants with their mature siblings have found no striking difference between the two groups after the first few years of age, and she suggests the possibility of an economic handicap continuing to act on the premature infant after birth.

Drillien's figures are of necessity based on a selected section of the population, but they are a valuable addition to the other published analyses. Crosse,⁵ for instance, investigated the records of 85,305 births which took place in the city of Birmingham during the years 1943 to 1946. She found that the prematurity rate was 6.9%, and that 42.8% of the stillbirths and 57.8% of the neonatal deaths occurred in premature infants. The causes of prematurity, stillbirth, and neonatal death were similar to those reported by Drillien, with the exception that mortality due to erythroblastosis was lower, such cases naturally being collected in hospital. The influence of social and economic factors on prematurity, stillbirth, and neonatal death was demonstrated by Baird,⁶ who analysed the records of 10,728 Aberdeen births and grouped them according to the different social classes. He found that the rates of prematurity, stillbirth, and neonatal death were all much greater in the poorer classes than in the better-off. The commonest obstetric condition associated with prematurity was toxæmia, and this was twice as common among the poor as the well-to-do.

All these investigations show that if the risks of prematurity are to be further reduced the interests of individual midwives, doctors, antenatal clinics, and hospitals must be merged in the general interest of obtaining the best result for each mother and her baby.

"DOGGER BANK ITCH"

Occupational diseases are often given graphic names which indicate the cause or the striking features of the lesion. "Dogger Bank itch," recently described by Bonnevie,¹ is an eczematous dermatitis observed in North Sea fishermen, particularly those fishing the Dogger Bank area, and is due to contact with the sea chervil, a seaweed-like animal colony, the coralline *Alcyonidium hirsutum*. It is rare for live animals to cause contact dermatitis, which is generally the result of chemical or vegetable irritants. The sea chervil is landed, sometimes in large quantities, in the nets with the fish and is thrown back into the sea. Bonnevie describes the case of a young Esbjerg fisherman who had been fishing the Dogger Bank for four years. The dermatitis started on his hands and cleared rapidly when he went ashore: on returning to fishing increasingly severe attacks

developed, with blistered and oedematous eruptions on the hands and arms, face and legs. Some men have had recurrences of the condition after attendance at fish auction rooms and as a result of journeying in an inspection ship over the Dogger Bank area without actual fishing. Bonnevie suggests that inhalation of the allergen from the atmosphere may be responsible for such relapses. Patch tests have been performed with material obtained from the inner and outer surfaces of the sea chervil and from expressed juices; these were all positive in the affected subjects but negative in controls. The disease has figured in the Danish Workmen's Compensation Act since 1939.

AFTERCARE OF THE HOSPITAL PATIENT

There are many signs that hospitals are now taking a close interest in their patients at home and at work, as well as in the ward or out-patient department. In the work of after care there is some doubt about when the hospital almoner should withdraw and the health visitor take over. An attempt by the Ministry of Health¹ to lay down a line of demarcation has been criticized by the Institute of Almoners, which does not agree with the instruction that "the almoner will not visit patients in their homes." In a leading article *The Times*² takes the side of the almoner on the grounds that so long as a patient is the responsibility of a hospital the social aspects of the patient's care should remain with the medical social workers on the hospital staff just as the medical care rests with the hospital doctors. Commenting on this, Dr. Fraser Brockington³ suggests that the difficulty is due to the fact that the health services have been divided administratively into three parts. "The time will come," he writes, "when such a division will no longer exist. Until then there must be a clear definition of responsibilities."

Almoners were first employed at hospitals to assess charges and sometimes to recover them; now they provide for the hospital medical staff the "background histories" which are needed for the full understanding of individual cases of illness. Health visitors' duties have also been widened. At one time they were employed solely for the purpose of reducing infant mortality; now under the National Health Service Act the welfare of the whole family, in health and sickness, is their concern.

Patients returning home from hospital can certainly be given valuable help by experienced social workers, whether almoners or health visitors. Already some hospitals, including one or two smaller ones which had never employed almoners, have been using health visitors for various purposes. In one area a health visitor was able to find accommodation for some elderly patients who had been occupying hospital beds for many months. In Cardiff health visitors have been calling regularly on patients discharged from hospital after treatment for diabetes and peptic ulcer. The scope of this work is wide, and the public will certainly appreciate any help of this nature which can be given. It would be a pity if the administrative line which separates hospital from health authorities gradually assumed the appearance of a railing with spikes. The right course is to make the best possible use of the almoner's training in social case-work (whether or not this involves home visits) and of the health visitor's training in nursing and health education. There may be a problem in theory, but there should certainly not be one in practice wherever health authorities and hospital management committees are ready to co-operate in order to provide the best service for the patient.

VIRUS RESEARCH AND THE VIRUS PROBLEM

LONDON UNIVERSITY LECTURE

Dr. Pierre L  pine, of the Pasteur Institute, Paris, gave a special University of London lecture at the London School of Hygiene and Tropical Medicine on Feb. 8.

The first study of the physical properties of viruses, he said, was directed to the determination of their size. As early as 1923 it was shown that groups of viruses were of different sizes. Here he referred to the important work on ultra-filtration carried out in this country by W. J. Elford from 1929 onwards. Colloid membranes were prepared with a given size of pore, and determinations of the size of many of the commoner viruses were made. The methods which had been developed since had served only to make more precise those original measurements. All that the early workers were concerned with was an accessory physical characteristic—namely, ability to pass through filters. Later experiments showed that some virus particles were of different shape, but none of these observations controverted the opinion that the viruses were essentially minute micro-organisms. Dr. L  pine mentioned the work of Stanley, who regarded the tobacco mosaic as a giant molecule and explained how virulence and infection came to be associated not merely with a definite chemical structure but with physical properties. This became the widely accepted view, and was generalized rather hastily to include all viruses.

The virus problem was being attacked by chemical as well as by physical methods, but Dr. L  pine disregarded the former, as they belonged essentially to a special branch of research into proteins. He reviewed the physical methods which had contributed to a knowledge of the virus. The use of filtration with membranes remained the simplest and most direct laboratory procedure, but another useful procedure was centrifugalization, which gave accurate information about the size and density of the virus and revealed the size distribution. Delicate but remarkably efficient instruments had been built for this work, which had been carried out under difficult conditions during the past few years at the Pasteur Institute.

The virus density measured by ultra-centrifuging could be compared with the size obtained by filtration. He described another procedure which had been developed for estimating virus size. This consisted of placing on a revolving machine an ampoule containing a virus the titre of which was known and irradiating with radium or x rays. Later the titre was again worked out and it was ascertained how much of the virus had been destroyed by a given amount of radiation. It was inferred that the whole of the virus substance was radio-sensitive and that the structure was homogeneous, but in animal strains it appeared that the sensitive area of the surface was not more than half the whole, and therefore the existence of different zones appeared likely. The structure of the virus, therefore, was not homogeneous.

Electron Microscopy

The coming of the electron microscope had made it possible to check visually the morphological data. In some cases the electron microscope had revealed structures infinitely more complex than might have been expected from the use of other methods. Dr. L  pine here showed a photograph of an electron microscope which was built in secrecy in Paris during the German occupation. It had now been turned into a commercial instrument, and was in use at the Pasteur Institute. By means of this instrument it was possible to sort out the viruses in groups according to size. At the top of the size scale (300 m  ) were such elementary bodies as the psittacosis group of viruses, which in structure and behaviour were closely related to the rickettsia. It seemed necessary to conclude that the viruses of this group had an organization not unlike that of the bacterial cell. Then, going downwards in the scale, came the animal poxes, and then the phages, their morphological characteristics suggesting that they were mere collections of molecules. By centrifugalization it was possible to break the phage up into its individual parts, the head, consisting of a nucleus within an envelope, and the tail. There was less detailed knowledge about a virus such as the influenza virus, but there was reason to think that it was not more

homogeneous than the phage. Further down were more elementary forms of virus, the virus of foot-and-mouth disease (diameter 10 m  ), and insect viruses.

Animal viruses had a wide range of size and structure, but none of them seemed to answer the description of a "giant molecule." Of plant viruses more than two hundred were known, and among these only about a dozen had been obtained as homogeneous protein found in living matter. All these viruses contained pentose sugar, which in the case of tobacco mosaic had proved to be ribose. Plant viruses of low phosphorus content were rod-shaped, and tended to take the form of long chains. Those with a higher phosphorus content formed particles.

Under the electron microscope it was possible to see that the crystals in the tobacco mosaic were the result of an agglomeration of particles tending to collect in long chains.

This invisible world, said Dr. L  pine in conclusion, comprised a vast and varied population, from the nucleoproteins up through organisms of increasing complexity. The notion of viruses as giant molecules was very attractive to some, but he thought it introduced a misleading simplification of the problem.

TRACER ELEMENTS IN BIOLOGICAL RESEARCH

Radioactive isotopes are being used increasingly in biological research. Much work has been done on the subject in this country, and more in the United States. Professor F. A. Paneth, F.R.S., in two recent lectures to the School of Pharmacy in London, stated that experiments were taking place with a number of hitherto unfamiliar chemical elements. In the biological laboratory of the near future there might be in use seven or eight elements so far scarcely known, but which might become as prominent in this field as radioactive phosphorus, the first isotope produced for medical research, or radioactive carbon, the classical example of a tracer element in biological experiment. He mentioned in particular "astatine," a chemical element behaving in physiological experiments very much like iodine. Little was known about it as yet, but it was said to offer interesting possibilities in view of its characteristic concentration in a particular part of the body.

The most extensive researches were now being carried out with iodine rather than with carbon or phosphorus. Professor Paneth showed charts illustrating how in animal experiments iodine was taken up by the thyroid and to a much smaller extent by the liver. Other charts showed the relatively diffuse distribution of radioactive phosphorus as compared with the heavy concentration of radioactive strontium in the bone. Strontium was deposited almost exclusively in the bone shaft and hardly at all in the osteoid matrix, whereas plutonium gave a heavy deposit in the matrix and appeared only superficially in the shaft. The use of all these radioactive substances, as Professor Paneth reminded his audiences, was potentially dangerous. If too much iodine were used, for example, the physiological condition seemed to alter and the substance acted more or less as a toxin. One of the surprises of recent years had been the smallness of the amount of radioactive substance which might have a dangerous effect, and it was not without significance that many of the early workers in the radioactive field died from pulmonary disease. Consideration had also to be given to the choice of the right isotope for biological experiments. The half-life must not be too long nor the tracer too strongly active.

Professor Paneth concluded by referring his hearers to the latest sources of information on the subject, adding, however, that the development of the new science was so rapid that no publication could keep abreast of it. The most recent compendium was the fourth report of the U.S. Atomic Energy Commission.

The British Council arranged for Dr. K. J. Powell, anaesthetist to Sheffield City General Hospital, to go to Italy on Feb. 21 to give a three months' course on anaesthesia at the Istituto di Patologia Chirurgica in Rome and to lecture in Florence and Milan. He has been invited to go to Rome by the Director of the Institute, Professor Valdoni, and the visit is a sequel to a wartime meeting. While Dr. Powell was stationed near Florence with a neurological unit he acted as anaesthetist for Professor Valdoni at the Italian civilian hospital in Florence.

Preparations and Appliances

AN IMPROVED JACK FOR THE BOYLE-DAVIS GAG

Mr. TERENCE BANHAM, assistant E.N.T. surgeon, Royal Cornwall Infirmary, Truro, writes: Various methods have been devised for maintaining the airway when using the Boyle-Davis gag for tonsillectomy. Negus's jack (*B.M.J.*, Sept. 19, 1925, p. 523) and the Guy's model suspension rod with ratchet chest-plate are perhaps the best known. These methods are satisfactory in the majority of cases; but they are not ideal, particularly in children. They both exert pressure on the chest, and the Guy's method, though the more secure, utilizes a strap round the patient's neck which by pressure on the neck veins tends to interfere with the venous return from the head. This disadvantage can be overcome by using a much longer strap passing round the head of the table, but the plate still exerts pressure on the chest and, in very small children, on the upper abdomen.

The appliance here described makes use of the Guy's chest-plate but overcomes its disadvantages by holding it rigidly just above the patient. The stand is made of $\frac{1}{2}$ -in. (1.8-cm.) diameter galvanized iron tubing bent as shown in the photograph. The rectangle holding the chest-piece is filled in by

brazing a metal plate to the three sides, forming a platform. The side members of this rectangle are slotted and the Guy's ratchet breast-plate is attached to the top of the platform by two bolts with winged nuts, so that it can be moved backwards and forwards. The two vertical rods fit into holes which are standard fittings on many operating-tables (i.e., Watson Williams's E.N.T. table, made by Chas. Thackray, and the Allen and Hanbury's operating-table). If this rod is a fairly tight fit the whole apparatus is held rigidly by the backward pressure of the suspension rod. On the A. and H. table the rods fit into a sliding collar which is supplied with a lock-nut.

This appliance has been used for many months in the ear-nose-and-throat theatre of the Royal Cornwall Infirmary and has been found entirely satisfactory. It was designed and made for me by the hospital engineer, Mr. Fred Toy.

The first number of the *International Digest of Health Legislation* has recently been published. It will be recalled that the duties and functions of the Office International d'Hygiène Publique have been transferred to the World Health Organization. One of these duties was the publication of the *Bulletin Mensuel de l'Office International d'Hygiène Publique*, which first appeared in January, 1909. The *Bulletin Mensuel* continued its work until December, 1946, and published a great deal of information about public health legislation, communications and vital statistics, as well as many technical reports. In future the technical reports will be incorporated in the *Bulletin of the World Health Organization*, while what was the first section of the *Bulletin Mensuel* has now become the *International Digest of Health Legislation*. The *International Digest* will print translations of, or extracts from, the texts of the most important laws and regulations dealing with public health and related subjects in different countries. There are separate editions in English and French and each edition is issued in two forms—as a bound volume, and as a collection of separate fascicles in a loose cover.

Reports of Societies

THE HEART IN ENDOCRINE DISEASE

At a meeting of the Section of Endocrinology of the Royal Society of Medicine on Jan. 26 Dr. WILLIAM EVANS read paper on "The Heart in Endocrine Disease."

Dealing first with disease of the thyroid, Dr. Evans said that the finding of abnormal circulatory signs could be a valuable aid to diagnosis. When paroxysmal fibrillation occurred with a swelling of the thyroid, thyroidectomy might often end the arrhythmia, but this did not always happen, presumably because the thyroid condition was not the cause; established fibrillation found in hyperthyroidism was as a rule a sign of heart failure. If fibrillation persisted for ten days after operation quinidine therapy should be started. Two-thirds of such cases might be expected to return to normal without this; half the remainder would respond to quinidine, and the rest would continue with fibrillation, but at a slower rate. The persistence of fibrillation was not unfavourable, and digitalis need not be given unless exercise produced uncomfortable palpitation. He did not believe that cardiac enlargement progressed when the cause had been removed by thyroidectomy. Thyroid toxæmia might cause distension of the left auricle indistinguishable from that found in mitral stenosis. The speaker went on to discuss the heart signs in myxoedema and cretinism.

Speaking of acromegaly, he said that it was his experience that the heart did not show any changes in this condition, but in gigantism there might be generalized enlargement of the heart. After showing some electrocardiograms to illustrate abnormalities found in pituitary deficiency, Dr. Evans spoke of the heart in Addison's disease. In this condition, he said, the patient coming for investigation and treatment requires the services of the endocrinologist and the cardiologist. Many of the cases presented for diagnosis were doubtful examples of Addison's disease, and the help of the electrocardiogram was indispensable. Repeated electrocardiograms might prove a reliable guide in the control of therapy.

Addison's Disease

It was well known that the blood pressure was low in Addison's disease; hypotension was probably the most constant single physical sign. It was common to find the systolic pressure lower than 100 mm. Hg, but its reaction during successful salt therapy was not as well known. During treatment it might rise to normal, and sometimes hypertensive developed. Cases in which a low blood pressure persisted were many, and their progress in other respects might be satisfactory; in circumstances such as these it was difficult to judge progress during salt treatment.

Although a normal electrocardiogram did not exclude the diagnosis, a warning should be issued against accepting without due care in this circumstance a diagnosis based on suspicious clinical signs. This problem needed more attention. In studying the abnormal electrocardiogram it would be well to consider the changes in two groups. That changes might develop owing to excessive salt therapy was suggested from an experience of eight cases. Salt treatment first corrected the changes due to Addison's disease and then exerted its own influence on the tracing. If this was confirmed in the future an instrument of great value would be placed in the hands of the therapist dealing with Addison's disease. Treatment would aim at correcting the inversion of the T wave, restoring physiological electrocardiogram, and stopping short of inducing such inversion. After showing electrocardiograms in typical cases of Addison's disease, Dr. Evans said that although he left the story unfinished he hoped that what he had said had emphasized the fact that the investigation and treatment of any patient remained incomplete without electrocardiography.

The heart in Addison's disease was small owing to the reduced blood volume peculiar to that condition. Periodic radiological examination was a necessary accompaniment

treatment. Some degree of enlargement of the cardiac silhouette was to be expected as an effect of treatment, but greater increase should be avoided, and the appearance of conspicuous hilar shadows signified early death unless salt was withdrawn immediately.

With regard to other endocrine disturbances, he could not speak authoritatively on the gonadotrophic hormones, but in two cases of stilboestrol treatment for cancer of the prostate he had seen hypotension develop, although no such change had taken place from the same treatment in six women with carcinoma of the breast. It was reported that heart pain could result from too much insulin in diabetes—the so-called “insulin angina.” It was difficult to decide whether the relationship was causal or casual. In diabetic coma the electrocardiogram was often altered.

In conclusion Dr. Evans said that he had not pretended to give an authoritative treatise on the way in which the heart felt the impact of all endocrine diseases, but he thought they should examine the deficiencies in their knowledge of this section of medicine.

Dr. RAYMOND GREENE said that he agreed very largely with Dr. Evans when he said that two-thirds of the patients with thyrotoxic fibrillation recovered as a result of thyroidectomy, and about half the remainder recovered on quinidine. After he had seen his hundredth case of thyrotoxic fibrillation, he worked out the proportion of recoveries, and it coincided with Dr. Evans's suggestion. He had had one case of a patient with typical angina of effort who was found to have diabetes mellitus. She was admitted to hospital and stabilized and had never had angina of effort since. He was not convinced that thyrotoxicosis was a cause of hypertension. Hypertension occurred in patients with thyroid disease in about the same proportion as in the general population.

Dr. CRIGHTON BRAMWELL referred to the peculiar third sound heard at the right apex in thyrotoxicosis cases and which often gave rise to a suspicion of mitral stenosis. During the war when examining recruits this problem was frequently encountered. The question would arise whether a man had mitral stenosis, and very often there was evidence of slight thyrotoxicosis or else of an overacting heart. The sounds in the two cases were almost identical.

Dr. EVANS replied to the discussion.

EVALUATION OF RENAL CLEARANCES

In the Section of Experimental Medicine of the Royal Society of Medicine on Feb. 8 there was a discussion on the evaluation of renal clearances.

Professor R. A. McCANCE, F.R.S., in introducing the subject with Dr. J. R. ROBINSON, gave a definition of clearances, and discussed their physiological significance. He reviewed the various substances which had been used to measure the glomerular filtration rate and renal plasma flow. Speaking of urea clearance, he said that this was a valuable measure of renal function, though its precise significance was in some doubt. In chronic interstitial nephritis the urea clearance followed the progress of the disease, but it was less easy to say what it measured. In health, and when the urine volumes were high, the urea clearance was usually about 70% of the glomerular filtration rate; but in disease, while it was still probably some measure of that rate, instances had been reported in which it equalled or even exceeded it as measured by the inulin clearance. Nevertheless, the fact that urea clearance was an excellent measure of the progress of the disease was not disputed. The significance of all these clearances was much more problematical in disease than in health; he could multiply instances in which the physiological clearance ratios were upset, and no one knew on which of the two to rely.

Further problems had arisen since the function of the kidney in very young children had been studied. To begin with it was convenient to be able to refer the infant data to some standard used for adults. In children, after the age of about eighteen months, clearances seemed to vary fairly closely with the surface area, so that once the surface correction had been

made the baby could be thought of as an adult. But earlier than eighteen months, and especially in the very young infant, the clearances were very low, though there was no evidence whatever that such clearances were abnormal. Here again the exact significance of these clearances in the infant was not known. The inulin clearances seemed to measure the glomerular filtration rate, although this had not been tested out in infants as it had been in adults and in animals. Those who had measured diodone clearances at low levels of plasma concentration had found them low relative to the inulin clearances, and so high “filtration fractions” had been obtained. Could it be assumed in these circumstances that the diodone was measuring the effective blood flow through the kidney? Another interesting thing about the function of the tubules in young children was that the exogenous creatinine clearances were not consistently higher than the inulin clearances, as in the adult. They were in fact equal to the inulin clearances, so that there was evidence that creatinine was not excreted from the plasma to the urine by the tubules of the infant. Professor McCANCE concluded what he described as a provocative opening by repeating that little was really known about the significance of renal clearances in disease. Asked about the use of these substances clinically, he said that in his view inulin or diodone clearance was not of any particular value, but it would be interesting to hear what people with clinical experience had to say. He was content with urea clearance.

Effects of Anoxia

Professor KENNETH J. FRANKLIN showed a colour film made recently in the Department of Physiology at St. Bartholomew's Hospital illustrating the effect in the rabbit of anoxic diversion of the renal cortical blood flow. The existence of the “shunt” seemed to add, he said, to the difficulties being discussed. In the film, to permit closer study of the superficial visible changes, the left kidney was exteriorized. Free air entry into the trachea was restricted, and during the development of anoxia the kidney surface was seen to shrink in size, become wrinkled, and commence to pale. With free air entry the kidney surface rapidly flushed and then became red all over, but the wrinkling persisted for an appreciable time for some reason now being investigated.

Dr. J. A. BARCLAY brought forward certain observations which he said could be explained only on the basis of a three-component system of excretion—namely, filtration, secretion, and reabsorption. The discussion was continued by Dr. D. A. K. BLACK, Dr. W. T. COOKE, Professor ROBERT PLATT, and others.

Professor C. W. WILSON said that the urea clearance test was not readily applicable in hospitals as a routine, and yet it was true to say that it could yield much information. What he desired to see was a simple test applied in hospital, one which would not be subject to gross errors, and which might yield much earlier information concerning kidney reserve. He wondered whether endogenous creatinine clearances might be the answer as a measure of diminished glomerular filtration before the blood urea rose.

Professor McCANCE said that Professor Wilson's was a very difficult question to answer. Nobody knew what they were measuring when they measured endogenous creatinine. The difficulty was the chromogens, which were present in the plasma in variable amounts and reacted with the reagents. Until an absolutely specific method of estimating creatinine was available, so that the amount of creatinine normally present in plasma could be simply and easily established, it seemed useless to talk in quantitative terms about endogenous creatinine clearances.

Professor H. P. HINSWORTH, who presided in the absence of the president, Professor G. W. PICKERING, asked whether there was any real evidence that urea clearance was a test of renal function. Dr. J. R. ROBINSON, in reply, argued that while the urea clearance test would show that the kidney was not functioning normally, and would give some idea of how badly it was functioning, it would not distinguish between renal insufficiency due to abnormalities in the kidney and renal insufficiency due to extra-renal causes.

INTERNATIONAL STATISTICS

In a discussion on international statistics at the January meeting of the Royal Statistical Society, Dr. PERCY STOCKS, chief medical statistician at the General Register Office, described recent efforts to secure co-operation in the international field so far as mortality and morbidity statistics were concerned.

He believed that a greater degree of international agreement had now been reached concerning statistics of disease and death than about statistics of any other kind. An international list of causes of death had been in existence for fifty years and had been revised at international conferences of statisticians and medical experts. Two urgent needs had presented themselves: the first to obtain a classification of diseases and injuries apart from mortality, and the second to obtain agreement on methods of dealing with death certificates on which more than one cause of death was stated: more than half the certificates now gave multiple causes. He and Dr. Dunn, chief vital statistics officer in the United States, met after the international conference in 1938 and resolved to pursue these matters. Then the war came and Great Britain, the United States, and Canada were caught unawares without the morbidity classification which was urgently needed.

A committee of the Medical Research Council in this country set to work and produced a classification of diseases and injuries which had been widely used. At the same time, about 1944, a somewhat similar classification was produced in the United States. Fortunately both these classifications were based on the framework of the international list of causes of death, and it seemed possible to arrive at an agreed classification which would serve the purpose both for mortality and morbidity. This would do away with the ridiculous position whereby a soldier admitted to a military hospital, then transferred to a civil hospital, and afterwards pensioned off, might have half a dozen code numbers for the same illness, and if in America or Canada different numbers. At the end of 1945 Dr. Stocks went to Washington, and the first difficulties of settling the general principles with a large commission of American experts were overcome. A small working party was set up which in two months hammered out an agreed basis with the help of numerous specialists. This was intensively studied by a medical advisory committee, revisions were considered, an interim committee was appointed by the World Health Organization, and the list was circulated to seventy countries for their criticisms and comments. Replies were received from about forty, and at a subsequent meeting in Geneva as many of the amendments as were appropriate were incorporated. Meanwhile the United States and Canada decided to adopt the English system if this was approved by the International Conference of Statisticians held in Paris last year. The conference did approve, and approval was also given by the World Health Assembly.

It was decided to print the new manual in English, French, and Spanish and to produce a set of international regulations which would be obligatory from 1950 onwards unless a nation decided to contract out. The regulations required the use of the English system of notification of causes of death. The manual with the new classification was now on the way to Geneva, and should be available in London in a few weeks' time. The consequence of all this would be, Dr. Stocks added, that if he happened to be riding a bicycle and was knocked down by a taxi and got a septic compound fracture of the tibia, whether it happened in Hampstead or in Amsterdam, Copenhagen or Baltimore, his number—an eight-digit number—would be the same.

MANCHESTER PAEDIATRIC CLUB

The Manchester Paediatric Club was inaugurated on March 15, 1948, with a membership of twenty-five. Dr. Catherine Chisholm, C.B.E., was elected president, and Professor Wilfrid Gaisford is the secretary. Three meetings are to be held annually.

At the first meeting on July 7, Professor EDMOND KERPEL-FRONIUS, of Hungary, read a paper on "Body Fluids in Dehydration and Malnutrition," and Dr. M. L. THOMSON followed with "Notes on the Use of Arabin in Gastro-enteritis." The second meeting was on Oct. 5, when Dr. DOROTHY ANDERSEN, of New York, read a paper on "The Treatment of Coeliac Disease."

The first annual general meeting was held on Jan. 7, 1949, with a scientific session consisting of six papers in the morning, and a discussion in the afternoon on "Methods of Improving the Child Health Services." The annual dinner followed. The next meeting will be on May 9, when the lecturer will be Professor Lichtenstein, of Stockholm.

ACCIDENTS IN THE HOME

At a meeting of the Society of Medical Officers of Health held on Feb. 17 at Tavistock House, Dr. C. A. BOUCHER, a medical officer of the Ministry of Health, read a paper entitled "Can the medical officer of health help to prevent home accidents?" Sir ALLEN DALEY was in the chair.

Dr. Boucher said that the 6,000 fatal accidents which occurred annually in homes in England and Wales accounted for almost one-third of the total number of accidental deaths in the country each year. Apart from the fatal accidents it was reasonable to suggest that there were possibly 60,000 non-fatal home accidents of moderate severity each year. There had been over the last ten years no fall in the number of fatal accidents. On the contrary, in the two age groups under 5 years and over 65 there had been some increase. More children under 5 years lost their lives as the result of an accident in the home than from accidents on the roads.

It was probable that accidents were fairly evenly distributed throughout the country. This was confirmed by an analysis of fatalities from burns and scalds in the 83 county boroughs in England and Wales during the last three years. Surveys of home accidents suggested that the majority were preventable. In support of this Dr. Boucher referred to an inquiry made in 1943 by Dr. Marion Wright in Glasgow, from which she concluded that squalid living conditions, with overcrowding and a low standard of intelligence and conduct associated with them provided the background to the majority of these accidents. It was difficult to say what part was played by structural defects in the home; it was not believed that existing house design was a major cause, although it contributed to errors of judgment and carelessness. Dr. Boucher quoted an analysis of 504 burns and scalds which were admitted to the M.R.C. Burns Unit of the Birmingham Accident Hospital during the three years from 1945-7.

Three-quarters of the accidents in the home were provided by two types of injury. Falls accounted for 60% of the fatalities, and the large majority of these occurred among the elderly, while burns and scalds accounted for 15%, and these affected mostly children under 5. Too little account was taken of the many elderly persons with defective hearing and limited eyesight who were subject to attacks of giddiness. In the case of the elderly special attention should be given to safe stairs, adequate lighting, and sufficient handrails.

Unprotected Fires

The unprotected coal fire was still the greatest source of danger to the young and old, but the electric fire, especially of the portable variety, was becoming more and more a menace, and existing legislation did not provide for the adequate guarding of electric and gas fires. Dr. Boucher stated that tea in any of its stages of preparation or consumption was the commonest single cause of scalds, and accounted for one-quarter of the fatalities, which occurred mainly in infants and young children. He went on to draw attention to the considerable increase over the last ten years in deaths from suffocation, mainly of children under 1 year of age.

He outlined what was being done to reduce home accidents but wondered whether this was sufficiently effective. He considered that there should be a more individual and personal approach, and doubted whether legislation, except with regard to the manufacture and sale of safe articles, could be effective. He suggested that the medical officer of health with his staff could contribute much of value, because of his intimate knowledge of conditions in his area and because he had access to the homes and could influence the people in the welfare clinics. In addition, he could arrange home safety exhibitions, and by means of lectures, pamphlets, and other propaganda could make his district "accident-conscious." The medical officer of health was concerned with the pre-school child, and in years to come

the problem of old people would become more urgent, in these two age groups the bulk of domestic accidents occurred. He suggested that the opportunity was there for the medical officer of health, and that it might be advisable to carry out a careful survey of accidents which had occurred in the district before undertaking propaganda and education to counteract them.

Dr Boucher mentioned the valuable work that was being done in some areas by the local education authorities through school teachers. He concluded by suggesting that the health visitor and sanitary inspector in routine visits could, by their influence and advice, eliminate accident-promoting hazards which existed in many homes and of which the occupiers were unaware.

LEEDS REGIONAL PSYCHIATRIC ASSOCIATION

The inaugural meeting of the Leeds Regional Psychiatric Association was held on Jan 29 at the General Infirmary. The objects of the association are to promote and improve the mental health of the individual and the community by the study of clinical social, educational, and administrative problems of the psychiatric practice in the region. In the course of a general discussion on the aims of the association Professor D R MACCALMAN who was elected chairman, expressed the hope that the meetings would be of social as well as professional value and that it would be possible for the assistant psychiatrists in the mental hospitals to make their contribution to the work of the association. Ordinary membership is open to specialists in psychiatry and trainees who are accepted by the association's executive committee. Associate membership is open to psychologists, psychiatric social workers and lay therapists practising in the Leeds region. The honorary secretary of the association is Dr J W Affleck.

CHELSEA CLINICAL SOCIETY

The fifth meeting of the session was held on Feb 8 at the South Kensington Hotel with the president, Mr NILS ECKHOFF in the chair. A discussion on the insidious onset of serious disease was opened by Dr DESMOND MACMANUS and continued by Dr HORACE EVANS. Both speakers replied to the subsequent discussion by Drs POCOCK, SUNDELL, CHADWICK, ATKINSON, ECKENSTEIN, STUART WEBB, SANDELL, HUGH GARDNER, NIALl MACMANUS, SIMPSON HARVEY, and Mr STEELER.

Certain sections of the Criminal Justice Act, 1948, involve the National Health Service. Section 24 confers upon courts of summary jurisdiction power to make orders for the reception and detention of offenders in institutions for persons of unsound mind. Where such an order is made it has the same effect in law as if it were a summary reception order made by a justice under Section 16 of the Lunacy Act, 1890. In most cases in which the question of action under this section arises the court will have remanded the person concerned for a medical examination and report on his mental condition under the provisions of Section 26. Before an order is made under this section the clerk of the court will normally ascertain, through the regional hospital board, the name of a hospital in which the patient can be received. However, where "catchment" areas have been allotted to mental hospitals, or as and when they are allotted, regional hospital boards should inform courts of summary jurisdiction in their area of the arrangements made in order to enable them to make the necessary arrangements for the patient's reception direct with the appropriate hospital. Subsection (3) enables payment of the usual allowances under the Witnesses Allowances Order to medical practitioners for attending and giving evidence for the purposes of the section. Section 26 enables a court of summary jurisdiction, where it is satisfied that the person charged with an offence, punishable on summary conviction with imprisonment, has committed the offence, to remand the offender on bail for periods not exceeding three weeks at a time for the purpose of medical examination and report on his physical or mental condition by a duly qualified medical practitioner. The court is empowered to make it a condition of his bail that he shall undergo examination at a specified institution or place or by a specified medical practitioner. The institutions and out-patient clinics in the National Health Service will be available to courts free of charge for this purpose. Unless the court for any special reason thinks it necessary that the medical practitioner who makes the examination should attend and give oral evidence, the report of the examination will be made in writing.

Correspondence

Plasma-cell Mastitis

SIR—Dr Max Cutler (Jan 15, p 94) has done a useful service by his excellent review of plasma cell mastitis in drawing attention to an uncommon lesion of the female breast which is of sufficient importance to merit more widespread recognition. Dr Cutler established this condition in the literature as a distinct entity with a characteristic clinical picture following a study of 10 cases in the year 1931,¹ and subsequent studies have served mainly to confirm the accuracy of his original observations.

In 1941, along with Dr M B Deckert, I reported a series of 24 instances of plasma-cell mastitis from a group of considerably more than 12 000 benign, malignant, and inflammatory lesions which had been treated at the Mayo Clinic.² At that time I thought that the condition must be an extremely rare one but since then, with access to a much more limited supply of clinical material, I have encountered three additional cases, and I now wonder whether a careful look out for these cases by clinicians would not be rewarded by the discovery of a large number of unrecognized instances of the disease.

There are two points which should be emphasized in considering the aetiology of the condition. In the first place, it has been observed only in parous women. In some cases as long as 25 years have elapsed between the last period of lactation and the appearance of the lesion, but lactation has preceded every reported lesion. Secondly, when the patient has been available for questioning the usual finding has been that for some reason or another she had not been able to use that breast for nursing purposes. In seven out of the Mayo Clinic series of 24 cases the nipple was congenitally retracted. In another case in the same series and in one studied later, the lesion had occurred in an accessory breast. I believe that the retention of milk in the breast for long periods forms the most satisfactory explanation of the cause of the lesion. It is easy to understand that the retained products of lactation, probably altered by the action of enzymes, might eventually find their way into the ductal tissues and there, by chemical irritation, set up the typical low-grade inflammatory response characterized by infiltration of plasma cells, epithelial atrophy, and the appearance of giant cells. It would also explain the phagocytosis of fat droplets which is such a marked feature of some of the sections and the discovery of fatty acid crystals in others. However, the most convincing argument in favour of this hypothesis is the experimental production of a similar picture by Rodman and Ingleby,³ who injected pancreatized milk into the breasts of virgin rabbits and pancreatic extracts into the breasts of lactating rabbits.

Although on section of the affected breast the lesion appears to consist of multiple discrete foci, tridimensional inspection were that possible, would reveal a continuous extension of the cellular exudate along the outer surfaces of the milk ducts embracing them in much the same way as ivy overgrows the trunk and branches of a tree. One effect of this process is the tendency to compression and obliteration of the duct system which prompted the earlier German authors to style the condition "mastitis obliterans." This is indeed the most characteristic feature of the lesion, and the term is to my mind preferable to "plasma-cell mastitis," because it is applicable to the many specimens in which plasma cells although present, do not predominate. However, if the conception of the aetiology of the condition as stated above could be regarded as proved "stale milk mastitis" would be an even more appropriate title.

Dr Cutler's description of the characteristic clinical sequence of a minor inflammatory episode characterized by pain in the non-lactating breast followed later by the discovery of a lump bearing all the hall-marks of malignant disease is admirable and there is no question that a typical history may give a clue to the diagnosis. But unfortunately this history is not always obtainable. Five of the 24 patients studied by Dr Deckert and myself gave no history of pain in the breast prior to the

finding of the lump. In these cases the condition could not have been suspected by clinical examination alone.

It has been suggested that "plasma-cell mastitis" can be diagnosed clinically. I think that the time has come when any surgeon who indulges in this type of guess-work should be brought to task for his errors. Biopsy is a simple and safe procedure and should be carried out in all cases of breast tumour. Any risk, discomfort, or inconvenience which may be occasioned to the patient by this trivial procedure cannot be weighed against the surgical crime, in the treatment of a lesion that may be malignant, of temporizing until the opportunity for its successful ablation has been irretrievably lost. In my experience the pathologist has had no difficulty in recognizing the inflammatory nature of the condition by the technique of quick-frozen section. The actual diagnosis has sometimes been in doubt, due to lack of acquaintance with the disease, but it has always been possible to rule out malignancy by this means. Some of the cases have been labelled "atypical tuberculosis," but the differentiation between the two conditions is not difficult when it is remembered that plasma-cell mastitis involves the ducts and periductal tissues, while tuberculosis usually has a perivascular and perilymphatic distribution. Furthermore, in tuberculosis typical tubercles are nearly always found, and they often contain caseous centres. In plasma-cell mastitis the tubercles are artifactual and caseation is not discernible.

The experiences of Rodman and Lübschitz¹ serve as a warning that major surgery should be delayed until after the subsidence of the inflammatory stage. Dr. Cutler's observations on the radiosensitivity of the lesion during this period are interesting, but in view of the morbidity of irradiation and the tendency shown by the lesions to subside spontaneously the time-honoured ritual of painting the part daily with iodine is probably all that is needed in the acute stage after the diagnosis has been established by biopsy. Local removal of the residual lump or simple mastectomy should be carried out when the lesion is no longer painful or tender. There is no indication for radical surgery. In the case reported by Gronwald² part of the plasma-cell exudate was left behind and no harm resulted.

I am not aware of any evidence to suggest a relationship between plasma-cell mastitis and carcinoma. Even if a case were to be reported in which the two conditions coexisted, the possibility of pure coincidence would have to be taken into consideration. Dr. Cutler's case of bilateral plasma-cell mastitis is the only one that has come to my notice. Two of the patients in the Mayo Clinic series gave a history of disease in the other breast, a cyst in one case and an abscess in the other. In the remainder the contralateral breast was free from disease. Dr. Cutler is to be congratulated on his discovery of this unique case.—I am, etc.,

Ottawa, Ontario.

Self-administered Trilene Analgesia

SIR.—May I from 8,000 miles away make some comment on the letters of Mr. F. Neon Reynolds (Sept. 25, 1948, p. 620, and Oct. 23, p. 761), and Professor R. R. Macintosh and Dr. C. Langton Hewer (Oct. 9, p. 691)? It seems to me that the latter two correspondents are constrained to base their criticism of the present "trilene" inhalers on the fact that they are not ideally "foolproof" as seen through the eyes of an advisory council for midwives. Nothing in this world is "foolproof": least of all the motor-car, or even the bicycle, provided for the midwife. I suggest that the very stairs up which she climbs to attend her cases have been responsible for more foetal and maternal morbidity than trilene (or any other) analgesia ever will be.

A year ago I presented¹ a preliminary paper on trilene analgesia as yielded from a small pocket inhaler, now known as the "trilene inhaler" (10 oz. or 284 ml.), covering over 2,000 cases, of which about one-third were obstetrical, including mid and high forceps, eclampsia, craniotomy, perineal repairs, etc. Results from this group bore a striking similarity to those obtained in over 50 other painful conditions—85% good, 9% fair, and 6% failures.

Since this time I have collated approximately 5,000 cases of the use of my inhaler, and there are probably 10 times this number unobtainable up and down this country, in England, and in other parts of the world. As is the way of our profession, I have no doubt whatsoever that I should have heard sharply and crisply had any untoward sequels arisen through its use. I have had no such report.

An even more important point is that in a very considerable proportion of the cases (all of which were of course self-administered) the patients were Africans, often of necessity left unattended for long periods of time with what has become known as the "white-man's pain pipe." Now, in matters of medicine the Bantu has a staggering disrespect for quantities, and it has been observed that the trilene ampoule of 6 ml. lasts usually a much lesser time than when used by the European, owing to the former's inhalational enthusiasm. Yet no report of effect on the child has been received, and, except for one observer who thought "the duration of the labour was slightly increased," none on the mother.

Drs. Helliwell and Hutton² state that trilene passes the placental barrier. So does chloroform, ether, cyclopropane, etc. These and nitrous oxide have a relatively ineffective phase of analgesia: trilene has a very marked one. The point of interest is, however, whether the quantity of trilene required to provide maternal analgesia will be such as to jeopardize the infant. As far as my results from this inhaler show, there is no practical effect.

Thousands of women are being permitted daily to suffer pain in childbirth when we have at our finger-tips the means greatly to relieve them. To my mind it is fantastic that what is considered satisfactory and safe is being withheld from many thousands of ordinary people because the intermediary—the midwife—is considered insufficiently intelligent to lift the curtain of pain for one in the drama she unfolds for two.—I am, etc.,

Durban, South Africa.

Haemolytic Disease of the Newborn

SIR.—Sir Leonard Parsons (Feb. 5, p. 234) has commented on our paper published in your columns of Jan. 22 (p. 123). It seems that the main point of controversy is whether the occurrence of kernicterus is or is not closely related to the severity of the haemolytic process.

In a letter to the *Lancet* on April 19, 1947, Sir Leonard Parsons wrote, "... there is no evidence that the products of haemolysis ever produce such damage [i.e., to the liver and brain]. Indeed the evidence is all to the contrary; for instance, changes in the liver and brain have never been described in congenital anaemia of the newborn in which the degree of haemolysis is greater than in icterus gravis." We summarized this letter by saying that Sir Leonard Parsons believed that there was an inverse relationship between the degree of blood destruction and the development of kernicterus, but readily accept his contention that we should have said that he had never found "any parallelism" between the two phenomena.

The causation of kernicterus remains obscure, but our observations strongly suggest that the condition is more likely to develop if the infant is anaemic at birth than if it is not. We have tried to show that this relationship is obscured by the changes in haemoglobin concentration that occur after birth; and we are not aware of any observations on cord blood which refute the evidence that we have obtained.—We are, etc.,

London, W.12.

MARIE CUTBUSH.

Diagnosis of Tuberculous Meningitis

SIR.—I have been reading with interest the recent correspondence on the diagnosis of tuberculous meningitis and should like to suggest that present investigators might do well to include an estimation of the blood/C.S.F. sugar ratio in their biochemical tests. In my series of cases examined ten years ago I found this estimation to be of greater diagnostic significance in the early stages of the disease than that of the C.S.F. sugar alone. It should not be forgotten that the convulsions

which so often mark the beginning of active trouble raise first the blood sugar and subsequently the C.S.F. sugar level,¹ and should the latter alone be estimated an apparently normal reading may be obtained. But this correlated with a blood-sugar reading taken at the same time will give a ratio below the lower limits of normality should tuberculous meningitis be present.

The level of C.S.F. chlorides is dependent on that of blood chlorides and is not, to my mind, of much diagnostic significance. If vomiting is a marked symptom, then they will both be lowered in the early stages, but I had several cases in which they approximated to normal even in the terminal stages of the disease. My results were published in detail in 1939.²

In view of the number of letters which appear in these columns drawing the attention of more recent workers to already published results which they have apparently overlooked, might I put in a plea that more use should be made of the *Quarterly Cumulative Index Medicus*?—I am, etc.,

Tuberculosis in the Family

SIR,—It may be interesting to recall some figures of my own which confirm the statement of Dr. C. O. Stallybrass in his excellent article "Tuberculosis at the Crossroads" (Feb. 5, p. 207). He says that "family contacts of known cases form at least one-third of the cases of tuberculosis." Some years ago with the help of all the London tuberculosis officers I was able to collect information on 6,933 new cases of tuberculosis with regard to their previous association with other cases of the disease within the intimate family circle.

In 2,167 instances, or approximately 31% of all cases, there was a history of household contact of some sort thought worthy of note, and in 350 of these there was more than one such contact. Investigation, however, concentrated on "important" contact—i.e., where a previously affected member of the immediate family was alive and suffering from tuberculosis, or where death had occurred from pulmonary tuberculosis in the immediate family within the preceding five years. A detailed analysis showed that 3,021 T.B.-plus male and 2,158 T.B.-plus female patients coming for residential treatment for the first time had been investigated and that the frequency with which contact with a previous case was noted was seen to diminish with increasing age. For instance, while 15% of all males with positive sputum showed previously important contact with the disease in the intimate family circle, the percentages ranged from 21 and 23 in the 16-20- and 21-25-year groups respectively, down to 10 in those over 40 years of age. As age advances a similar diminution in the importance of contact with a previous case was also seen in females.

Females throughout, however, showed a larger incidence of contact with a previously known case. Thus at all ages 22% had been in contact with a previous case in the intimate family circle, whilst the percentages ranged from 31 in the 0-15-year group down to 17 in those over 40 years of age. This greater incidence of contact as a factor in the causation of the disease in females as compared with males was thought to be due to the wider opportunities of exposure to infection in the family by reason of domestic and nursing duties. Kissing also might be a factor.

As regards the relationship of what might be called the "infecting" case, it was noted that the original cases were in parents in 20% in males compared with 27% in females. A tuberculous parent seemed to be a greater danger to a daughter than to a son. Here again the reason was possibly the special position of women in the household in regard to nursing and domestic duties and the like. Approximately three-quarters of all "infecting" cases were either living cases of pulmonary tuberculosis with positive sputum or cases which had succumbed to pulmonary tuberculosis within the immediately preceding five years.

I emphasized as a result of this work that contact with a previously diagnosed case of tuberculosis in the family was of sufficiently common occurrence in the history of new patients to stimulate examination of contacts in the attempt to find early cases, and I would agree now with Dr. Stallybrass that

data of this description should also stimulate us to press on with trials of vaccination by means of B.C.G. in these and other vulnerable classes of the community.—I am, etc.,

Brentwood, Essex.

Tuberculosis at the Crossroads

SIR,—In his interesting study of "Tuberculosis at the Crossroads" Dr. C. O. Stallybrass (Feb. 5, p. 207) throws some incidental light on a possible signpost which may be of value. Those of us who for long have been gravely suspicious that among nurses there was a relatively higher incidence of tuberculosis will have noted his words that, while the mortality rate in this group was not higher than among other young women of similar age, there "would seem to be a higher rate of morbidity." The distinction is significant and understandable, as nurses should be favourably placed as to early discovery and treatment, though at a higher exposure risk.

Surely, however, "higher morbidity," if recognized, should hasten the day for B.C.G. protection, in which this country has lagged so far behind Scandinavia. While statistics are lacking, there is little indication that our beds, closed for lack of staff, are being filled. Parents hesitate about health hazards for their daughters, and our profession is uneasy. If we recognize a signpost at the crossroads perhaps we may the sooner reach Norway's happy position of having "waiting beds" instead of the "waiting lists" of which Dr. Stallybrass speaks.—I am, etc.,

Northwood, Middx.

ESTHER CARLING.

Whither Tuberculosis?

SIR,—Now that Drs. G. Lissant Cox (Dec. 25, 1948, p. 1118) and A. S. Hall (Jan. 8, p. 70) have had their say and the *British Medical Journal* has made a pronouncement (Feb. 5, p. 226) on the above subject, may the voice of one who has worked in the tuberculosis service as long as the gentlemen mentioned, but who does not see eye to eye with them in this matter, be heard? Or are we to be told that *B.M.J. locutus est, causa finita est*?

To put the matter in its proper perspective a little personal history is necessary. I was appointed district tuberculosis officer by the Derbyshire County Council in December, 1918, on a salary of £500, plus the right to private consulting practice in tuberculosis and diseases of the chest. As I had come into the tuberculosis service from the Indian Medical Service the system of a fixed salary for public work combined with consulting fees for private work was no novelty to me. I soon found that in my district a chest disease of great clinical interest had long been known among the gritstone masons, ganister miners, and cutlery grinders, and naturally this condition and its supposed relation to pulmonary tuberculosis attracted my attention. When in due course the first silicosis compensation scheme was put into operation, the work of examining the employees in the scheduled industries devolved upon me. For this work I was, of course, independently paid.

Near Buxton is situated the research station of the Safety in Mines Research Board, and there I made the acquaintance of Professor J. S. Haldane and many other scientists interested in questions regarding the production of dusts in industry and their effects on health. I began to see in front of me possibilities of an interesting career and life study in diseases of the chest, and I built myself a house in Buxton with a consulting-room and a waiting-room for my private patients.

Alas, "the best-laid schemes . . ." The Home Office decided to "keep its ain fish guts for its ain fish maws," and appointed special district boards under its medical department for the routine examination of the workmen in the scheduled industries. Officially silicosis was taken out of my hands, but unofficially I continued to see suspected and established cases of silicosis and to make my investigations. Now, after thirty years, I can claim to have made some contribution to knowledge regarding that and kindred diseases.

In the nineteen twenties certain Divisions of the B.M.A. began to object to private consulting practice being undertaken by salaried clinical officers. The question became acute about 1924. Our division of the B.M.A. held a meeting in Derby and decided to support the right of clinical officers to private consulting practice. A resolution to that effect was sent to the Representative Body, and I was elected as divisional representative and directed to move the resolution at the Representative Meeting at Bath. There, alas, I made the greatest mistake of my life, a mistake which ever since I have bitterly regretted and of which I am thoroughly ashamed. The

Council of the B.M.A., alarmed at our resolution, had decided to modify, if not withdraw, its opposition to the right of clinical officers to private consulting practice and throw the onus of decision upon the local authorities. The Council of the Society of Medical Officers of Health agreed to this course. On the night before the meeting at Bath the chairman of the latter Council saw me, and tried to convince me that this move on the part of the B.M.A. gave us all we wanted and that in the circumstances it would be an error in tactics to move the Derby resolution. I could find only one colleague to consult, and unfortunately he agreed with the Society of Medical Officers of Health. Bewildered, against my better judgment, I gave way to the pressure, and at the meeting publicly withdrew the Derby resolution. I had fallen into the trap prepared by both Societies. Within a year my right to private consulting practice was taken away. As a solatium my salary was put up to £750, rising by increments to £935. But my freedom as a consultant was gone.

Time brings its revenges if only one lives long enough. With the Health Act of 1946 the wheel has come full circle. The old subordinate "tuberculosis officer" has gone, and the chest physician (not "tuberculosis physician," *pace* the B.M.J.) has come into his own. His consultant status is established. He will have beds at his disposal in the hospitals in his district. His usefulness in the preventive and rehabilitation spheres will be increased by his new status and the new facilities at his disposal.

Being on the wrong side of 70 years, I can only survey the promised land from its frontier and wish my younger colleagues and successors good fortune in their new freedom. If, with the privilege of the aged, I may be allowed one or two suggestions for their consideration, I would venture to say: Avoid thinking in woolly abstractions such as "the community," and regard your patients and their families as human individuals, every one of them unique, none of whom loses any rights as a human being by suffering from tuberculosis. Remember that an Englishman's house is his castle, which belongs to him and not to "the community," and which you enter at his invitation as a friend and counsellor and not of any right as a State policeman. Remember that there are greater evils than tuberculosis stalking through the land to-day, and that one of them is the submergence of the individual in the savagery of the mob, the triumph of the cheap slogan and facile shibboleth over reason and experience—in the words of Charles Morgan, "The totalitarian attempt to disintegrate the human personality by offering to weary and impressionable men the opportunity to collaborate in a false, artificial and tyrannical unity."—I am, etc.,

Chichester.

PATRICK HEFFERNAN.

Rights of Inventors

SIR,—May I raise a question of general interest, that of the rights of a surgical inventor in his inventions? According to present conventions anyone may ignore an invention, may recommend it, may decry it, or may modify it. I think this is all to the good, although I would suggest that modifications should not be made without (if possible) notifying the originator of the device. This may save him the not uncommon annoyance of having an early variation which he has abandoned for good cause brought forward by someone else as an improvement. I submit, however, that there is one treatment of an invention against which one is entitled to rebel: it is that of inaccurate description. The cause of this present protest is as follows.

Some twenty years ago I published a theory of the treatment of talipes consisting of three carefully worked-out steps, no one of which was effective without the others. They consisted of a manipulation far more drastic than any previously described, the continuous wearing of a splint affixed with sticking plaster until a full range of movement was gained, and the final use of a night splint to maintain this range. I had the greatest difficulty in getting the Arris and Gale Lecture containing this theory printed, owing to the disapproval of the orthopaedic authorities to whom the editors of journals submitted it. However, it was much taken up in the U.S.A., and in the normal course of events has now reached this country. Some of the descriptions of it now appearing in textbooks are sound. There is, for instance, an admirably clear and succinct summary in *Pye's Surgical Handicraft* (Wright, 1947), to which I would refer those who are considering writing it up but cannot spare the time to see it actually applied. Others, however,

are exasperating travesties. In *Recent Advances in Orthopaedics* (Churchill, 1937), for instance, there is a figure showing the foot being bandaged in to the splint while the footpiece is still on the cross-bar—which shows that the writer has not a clue to the mechanics of the device. And in *British Surgical Practice* (vol. 4, Butterworth, 1948) the same splint is shown with the leg piece cut off, while the letterpress asserts (as I can well believe) that this splint will not hold an infant's foot. I teach that an uncomplicated talipes can be fully reduced to six months of age—after that only needing the night splint—I am not pleased by this.

Surely easily avoidable inaccuracies of this sort are unfavourable in three ways. First to me, in making me appear to recommend devices that certainly will not work. Secondly to the purchaser of the book, who depends on it for guidance. And thirdly, and most important, to the patient, who, as I have only too good cause to know, loses the chance of early and complete cure while being treated according to hopelessly misconceived ideas of what I really do.—I am, etc.,

London, W.1.

DENIS BROWNE.

Infective Ear Disease

SIR,—Mr. C. M. Johnston (Feb. 5, p. 237) places us further in his debt by stating the incidence of central perforation, attitudinal perforation, and granulations in his cases of otitis media, and giving the result of treatment in each group of cases. One must agree with him that there is practical difficulty in advising operation in cases of "quiescence" or, as I would prefer to call it, persistent grumbling infection; and one must agree that occasionally with mere passage of time in the most unpromising case all active infection ceases. But exceptions make bad law.

Mr. S. R. Mawson (p. 238) agrees with me (Jan. 15, p. 11) in preferring dry toilet and powder insufflation to irrigation and his figures show how quickly effective such treatment can be. He advocates light insufflations with iodine-boric powder at daily intervals, fearing harm from heavy insufflations with penicillin-sulphathiazole-urea at longer intervals. His method has the advantage of proven value over many years, but I think his fears of the alternative suggested, with its less demand upon the patient's time, are exaggerated. Filling the meatus with powder does not in practice dam up discharge. Occasionally, all discharge apparently ceasing, the powder remains as concretions hiding the middle ear; this should be removed by forceps, crushing or curette, never by syringing. If removal not effected the patient should be told to attend again in a month, when no difficulty will present itself—in such a case there is no urgency.

Skin reactions are most uncommon (and incidentally were not quite unknown when boric powder was used), but an occasional heavy insufflation appears less liable to cause reaction than frequent light applications. The treatment is, of course, not to be repeated indefinitely; an early result is to be expected, and the case is unsuitable for the method.

It is suggested that silver nitrate prevents a detailed inspection of the middle ear. In chronic suppurative otitis media such inspection is not necessary every day, and in less than a week any obscuring effect has quite disappeared. To me the preparation is invaluable in treatment.

Mr. Mawson speaks of the essential prelude to powder insufflation, "meticulous dry mopping after suction of the middle ear with a Siegle's speculum." The need for this cannot be overemphasized.—I am, etc.,

Canterbury.

T. A. CLARKE.

A Clinic under the N.H.S.

SIR,—As one who has worked at the Institute for the Scientific Treatment of Delinquency for two years, I must say that Dr. Melitta Schmideberg (Feb. 5, p. 243) has been a little unfavourable both to the clinic clerical staff and to the National Health Service in her letter.

The staff's enthusiasm for paper work was well established long before the National Health Service took over; it is occasionally irksome, but it is the only clinic I have worked in that has never lost one of my patient's documents and nev-

made a mistake over an appointment. This service is so good that I now gladly comply with their administrative requests.

Delinquents are naturally the worst of all hospital appointment-keepers, but I find it no more tedious to wait for them when I expect to be paid (some bureaucrat at the North-West Regional Board having so far held up my proper contract) than when I was not paid. There is always something to read or write to fill in the odd half-hour—I am, etc.,

London NW 1

J F COOPER

SIR,—In your issue of Feb 5 a letter signed by Melitta Schmeideberg appears (p 243) under the above heading. This letter refers to the Portman Clinic (I S T D), which is the new name under the National Health Service of the clinic formerly administered by the Institute for the Scientific Treatment of Delinquency.

The letter was discussed at the next routine professional staff meeting of this clinic on Feb 7, which was very fully attended. At this meeting it was unanimously decided that we should write to you and state that the professional staff of the clinic wished to dissociate themselves entirely from both the spirit and the content of the letter. In particular they deplored strongly the criticism of the clerical staff, whom they expressly stated they had found to be courteous, helpful, efficient, and obliging and singularly free from the faults attributed to them in that letter—We are, etc.

DENIS CARROLL,
J D W PEARCE,
Medical Co-Directors

Portman Clinic (I S T D)

Heat and Blood Flow

SIR,—The annotation on heat and blood flow (Feb 5, p 230) is certain to disconcert many who use thermal agents to therapeutic ends. The news that more recent investigations carried out by Siems, Kosman, and Osborne support the well-established assumption that a temperature rise increases blood flow may therefore come as a relief to those who felt that the observations of Kemp and his co-workers were at variance with everyday experience.

A well-conceived "Comparative Study of Short Wave and Microwave Diathermy on Blood Flow" has led Siems and his co-workers to conclusions which they summarize as follows:

- (1) Short wave and microwave diathermy are equally effective in increasing local blood flow in the hind extremity of the normal dog.
- (2) Loss of motor or sensory innervation to the part does not affect the essential nature of the vascular response to heating.
- (3) Evidence is presented suggesting that the integrity of the sympathetic outflow in the dog is necessary for the typical vascular response to local heating.
- (4) There is no evidence that any known method of heating possesses properties which have specific effect on blood flow.

Oral Reactions to Penicillin

SIR,—As a mycologist I was interested in the review and investigations by Dr W G Cross (Jan 29, p 171) under the title "Oral Reactions to Penicillin." The striking similarity between it and the mycotic infection *lingua nigra pilosa* suggests the same aetiology. In support of this the following points, common to both conditions, are presented: (1) The oral erythema as seen about the third day. It constitutes the initial reaction to the irritation by the invading organism. (2) The discoloration of the tongue. This is due to the presence of the infecting fungus, the colour varying according to species. (3) The common site of the lesion, the hypertrophy of the fungiform papillae as well as the denuded patches on the tongue. The latter lesions are later reactions to the infection.

The micro-organisms found in the course of the investigation are normal inhabitants of the mouth and the cells diagnosed as *Monilia albicans* represent a variety of yeasts which are not determinable except after detailed culture study. At the same time the failure to demonstrate mycelium in the scrapings is

hardly an indication of their absence, as prolonged and patient search by a mycologist is necessary before a case is pronounced negative. Even then culture will often reveal their presence.

In conclusion, the oral reaction to penicillin may be explained on the basis of symbiosis. Penicillin, being a metabolic by-product of a fungus, will furnish in the mouth an ideally favourable environment for other species of saprophytic fungi—which occur in abundance and are both ingested and inhaled at some time or other—to thrive as facultative parasites. In the circumstances, apart from withdrawal of the penicillin lozenges, gum, or spray, which in any case are replaceable by other bactericides, fungicidal treatment should be instituted in the form of mouth-washes of Lugol's iodine and alkalis—I am, etc.,

Wembley Park, Middlesex

N GOHAR

Cancrum Oris

SIR,—May I add to Dr Donald Mackay's observation (Feb 5, p 223) on *cancrum oris*? I have seen this condition not infrequently in the Tropics and sub-tropics, and can certainly confirm that penicillin is effective in arresting the local progress of the disease almost immediately. This however is only part of the treatment, as *cancrum oris* is a manifestation of debilitated disease, which in tropical conditions may be due to any combination of tropical anaemia, sprue, chronic malara, kala azar, and worm infestation. A precipitating factor appears to be an infectious fever.

My first experience of this condition was in an Indian auxiliary in Assam. The patient had a spreading gangrene of the upper lip. Penicillin was given, and the spread was arrested immediately, a sharp line of demarcation forming. Then the gangrenous tissue sloughed without haemorrhage, but the patient died later of kala azar. I saw further cases of the disease in Mosul, Iraq, where judging by the frequency of the admissions to hospital, the condition must be not uncommon. I have no record of the numbers of patients treated, but they were considerable, and the value of penicillin had been well recognized.

The gangrenous areas became remarkably sharply demarcated after no more than 24 hours' penicillin treatment, and after separation a characteristic punched-out area was left. The gangrene was frequently extensive and deep, affecting bony structures—most frequently the adjacent alveolar margin—and often the whole of the superior maxilla bone would become bare, the teeth fall out, and finally a sequestrum separated. Fatality was rare, but the residual deformities in severe cases were hideous and the despair of the plastic surgeon.

One fatal case of which I have a record is that of a young woman who was admitted with a gangrene affecting the whole of the left face from forehead to mandible and excavating posteriorly to include the palate, leaving the globe unaffected, rendering no appearance revolting beyond description. Even in this case penicillin stopped the spread of the gangrene, but the patient died perhaps not unfortunately, of inanition.

I can confirm an occasional spontaneous cure of *cancrum oris*, having operated on a patient in Mosul—a young Kurdish woman—for a typical punched-out defect of the upper lip with loss of adjacent alveolar margin; the lesion was acquired in childhood following a febrile illness, when a piece of tissue fell away.

Regarding Dr Mackay's suggestion that the disease is infectious, I found no evidence of this in Mosul, where healthy children were admitted to hospital with the mother and affected child. I would suggest that in the case recorded there was a common predisposing factor—malnutrition, infestation or malara—and both children acquired some infectious disease precipitating the onset.

Perhaps in conclusion it may be of interest to record that in the one case of genital phagedaena under my care in Iraq penicillin was as effective as in cases of *cancrum oris*—I am, etc.

B BRENDAN HICKEY

Amethocaine Hydrochloride

SIR,—It is fair that I should confirm Dr P E Thompson Hancock's letter (Feb 5, p 236) on the subject of amethocaine anaesthetic fatalities as one of the cases reported by him was one of mine. This case had been gastroscopically preceded with no ill effects but on the second occasion received a considerable overdose. At that time (1937) the drug was not scheduled as dangerous and in trying to improve on the technique which

Dr. Hancock had taught me I was experimenting with a Schindler's anaesthetic tube. There was in this case no idiosyncrasy, as symptoms developed on the second occasion only.

Shortly afterwards it was my misfortune, though not through any responsibility of mine, to see a patient die in cocaine convulsions, again from overdose. The symptoms were identical—respiratory spasm, apnoea, cyanosis, and generalized convulsions following rapidly on each other. It seemed that there was not likely to be more than a few seconds for successful treatment of the established condition, and I should doubt if it would be feasible. Prevention is certainly the defence to rely on, and by the use of pastilles, supplemented by gargling, anaesthesia should be obtained with at the most 0.05 g. It is probably safer, if the throat remains irritable, to supplement local anaesthesia by general sedation, and on the advice of Dr. Avery Jones I have found intravenous injection—e.g., morphine—very helpful, and have had no anxiety from it.—I am, etc.,

Hove, Sussex.

W. A. BOURNE.

SIR,—We read with interest the article on amethocaine sensitivity by Mr. C. A. Jackson (Jan. 15, p. 99), for on the day of publication we experienced a similar near-catastrophe in which the picture was almost identical with that described.

Our case was a woman aged 71 admitted for gastric investigation. A gastroscopy was planned, and the fauces were painted with a total of 5 ml. 2% amethocaine solution. It is our practice to carry out this procedure with the patient seated facing the spot lamp and immediately to transfer the patient to the table, but in this case before the transfer could be effected she became distressed, made grunting noises, and became unconscious within 30 seconds of the completion of painting. She was lifted on to the adjacent table. Twitching of the facial muscles which rapidly progressed to general clonic spasm occurred, and pulse and respiration failed equally rapidly.

Resuscitation was commenced immediately, a steep Trendelenburg position being adopted, and inflation with oxygen by compression of the bag of a Boyle's apparatus was begun by one of us, while the other administered intravenous "pentothal" (1.5 ml. of 5% solution) and the surgeon scrubbed up for cardiac massage should it become necessary. The clonus ceased within one minute of the administration of pentothal, and intubation was now performed to facilitate inflation. The pulse became imperceptible at the wrist, and 10 mg. "methedrine" was injected intravenously. The pulse became perceptible, but with this improvement the clonus returned. Pentothal (1 ml.) controlled this, but the pulse failed again. A further 5 mg. of intravenous methedrine was given, and the pulse improved. The surgeon was now ready for cardiac massage and the abdomen prepared, but the pulse continued to improve and the respiratory movements began.

Within ten minutes in all of the onset of symptoms breathing needed no further aiding. A B.L.B. oral-nasal mask was applied, and the table gradually levelled. The patient was reacting to supra-orbital pressure within 30 minutes of the onset, and was returned to the ward after a further half-hour. She was drowsy all that day, but was her normal self the following morning. We had hoped to observe the effect of intradermal injection of 1 minim (0.06 ml.) of the amethocaine solution, but she refused all tests.

We feel that this case serves further to emphasize the possible danger of amethocaine sensitivity so admirably described in Mr. Jackson's paper, the existence of which as an entity has not in the past been universally appreciated.—We are, etc.,

G. J. REES.

J. H. WAKELY.

Liverpool.

SIR,—It is not surprising to me that Dr. M. McMinn (Feb. 5, p. 236) reports that a patient became unconscious after the injection of 4 ml. of a 2% solution of amethocaine hydrochloride. I have knowledge of a case where death occurred in a young adult after the injection of about 6 ml. of a 2% solution. This is a satisfactory concentration for surface anaesthesia, but is in my view forty times too strong for local infiltration anaesthesia.

My own experiences with amethocaine hydrochloride have been happy. I have used it over 5,000 times for gastroscopy (as a 25 mg. tablet or up to 5 ml. of a 2% solution) and well over 800 times as a field block for abdominal operations (350–400 ml. of a 0.05% solution with adrenaline), and in no cases were any toxic effects exhibited.—I am, etc.,

NORMAN C. TANNER.

London, S.W. 16

Specialization

SIR,—Specialization in medicine is a direct result of the inability of any one mind to assimilate the discoveries of many minds. It has phases of enthusiasm and growth, alternating with phases of disquietude and retrenchment. Specialization in every branch of medicine—e.g., neurology, psychiatry, paediatrics, and cardiology—has been resisted, and from time to time there are attempts to put the clock back in spite of the intellectual and practical fruits of such specialization. More recent specialties, such as endocrinology, in which I am particularly interested, have still to make appreciable headway against an understandable resistance.

Apart from innate conservatism, the causes of such resistance may be grouped under certain headings: (A) Too many specialists results in too few general physicians. (B) One cannot be a good specialist unless one has a sound general knowledge of medicine. (C) General medicine is too greatly impoverished and too severely drained by the specialists. These are valid. The solutions to A and B are obvious; to C less so, and C is therefore the greatest obstacle. In my opinion it can be solved in two ways. The general physician must be acknowledged to have an indisputable right to retain a sufficient number of "specialist" cases under his care throughout, so that his practice and teaching will be representative of all aspects of medicine: the specialist will still have in most big centres, a sufficient number of cases for the advancement of his own specialty. A specialist should always be available to give an opinion on a case under the care of a general physician colleague if so requested, but should never "claim" such a case for his own department, directly or by implication, or by common practice. This solution involves the spirit of humility and team practice, which, if accepted, will open up still further, as it has already done in some centres, the road to progress in the erudite and complex field of modern medicine.—I am, etc.,

London, W 1

S. LEONARD SIMPSON

Millilitres Correct

SIR,—Mr. N. A. Herdman (Feb. 5, p. 243) deplores the alteration of the abbreviation mil to ml. in the *British Pharmacopoeia*, 1948, and he gives reasons for his preference for mil. He could have added to these the fact that the Weights and Measures Regulations, 1907, give mil as the abbreviation of millilitre, and he thus has statutory authority on his side. Yet in spite of this I think that on balance it is to be preferred to mil, and perhaps the considerations below may incline Mr. Herdman to shift his sympathies in favour of ml.

There is a curious inconsistency in the Weights and Measures Regulations; the abbreviations for decilitre and centilitre are given as dl. and cl. respectively, and in conformity with them ml. might well have been expected for millilitre instead of m. To be consistent the regulations should be amended so as to substitute ml. for mil. Mr. Herdman supports the use of m. on the ground that it cannot be confused with any other measure. Actually, however, the term mil is also used as a linear measure representing one-thousandth of an inch. But perhaps the most important of all considerations from the practical standpoint is that scientific workers invariably use the abbreviation ml. and not mil, and the *British Pharmacopoeia* in adopting ml. has done nothing more than bring itself into line with modern scientific usage.—I am, etc.,

London, W 14

J. M. HAMILL

Marxist Genetics

SIR,—“To surround anything, however monstrous or ridiculous, with an air of mystery, is to invest it with a secret charm and power of attraction which to the crowd is irresistible. False priests, false prophets, false doctors, false patriots, false prodigies of every kind, veiling their proceedings in mystery have always addressed themselves at an immense advantage to the popular credulity, and have been, perhaps, more indebted to that resource in gaining and keeping for a time the upper hand of Truth and Common Sense, than to any half-dozen items in the whole catalogue of imposture. Curiosity is, and has been from the creation of the world, a master-passion. To awaken it, to gratify it by slight degrees, and yet leave some

always in suspense is to establish the surest hold that be had, in wrong on the unthinking portion of mankind' wrote Charles Dickens more than a hundred years ago. The use of the mysterious is characteristic of all appeals to emotion and is incompatible with reason. Communists have aged to attach an undefined kudos to such vague terms as 'identity,' 'proletariat,' 'dialectical materialism.' The Lyenko imbroglio is part of the same woolly propaganda. In order to assess truth in a situation of any complexity it is necessary to separate individual issues from one another and to investigate each critically by the scientific method. Dr John R. Baker writes in his admirable little book *Science and the Planned State* (George Allen and Unwin, 1945):

There has been much propaganda for Lyenko's methods of controlling the time of germination of seeds, and people might be led to think that 'vernization' was a Soviet discovery. An American test tells us, however, that the discovery was made in the United States before the Civil War (Sax K. 1944, 'Soviet Biology,' *Science* 98). The principle was certainly firmly established by Braem in 1898, in connexion with the germination of the resting reproductive eggs of animals (Braem, F. 'Untersuchungen über die Bryozoen aus dem Wasser,' *Bibl. zool.*, 1890, 2, (6), 1).

The proper critics of Lyenko's work are such as the established biologists. Doctors are little qualified to pronounce on scientific question and politicians not at all. But people with little real knowledge of biology and much enthusiasm for Communism will feel that by making much of Lyenko's theories they can receive a scientific cachet. Whether he has or has not in fact confirmed the earlier work referred to by Baker is simply a matter of scientific proof or disproof. Communists, however, wish to make it a matter of political propaganda, and trumpet the presumed demonstration that Communism can occasionally influence the germination of the members of the vegetable kingdom as proof that the social environment alters human evolution.

This is a complete *non sequitur*. In simple fact the difference between Soviet biological science and Western science is that the latter is prepared to acknowledge or to reject the facts according to the accepted rules of trial and error, argument and control irrespective of politics, whereas Soviet science will reject any fact, truth, or proved discovery, such as Mendelian hypothesis or the work of Morgan, merely because it is inconvenient to the Marxist ideology. To quote Lyenko: 'In order to get a particular result, one must want to get exactly that result.' The converse is clearly, 'If you do not like a result, that result is not true.' This may be good ethics but it is not science—I am, etc.,

London W 1

GEOFFREY BOURNE

POINTS FROM LETTERS

Animal Experiments

G. N. W. THOMAS (Penarth, Glam.) writes: Dr Michael C. Cullen (Dec. 25, 1948, p. 1122) raises issues over which, I am sure, many of our profession are deeply concerned from both the scientific and moral aspects. Dr Platten's view is that 'experiments involving animals in considerable pain, mutilation, in which life is long delayed, or prolonged misery (such as food or water starvation) are of doubtful value in the progress of clinical science,' and he refers to experiments in the U.S.A. whereby does the lower end of the aorta exposed, nine out of ten does died within one to seven days, with cold, cyanosed, and paralysed limbs. As in this country, as reported in one of our physiology books, kept alive in a laboratory for a year and a half after repeated removal of its cerebral hemispheres. Its utter misery from the operation can be imagined. As to does, Sir F. Treves (*Journal*, 1898, 2) said, 'From operations on does I have everything to unlearn,' Lawson Tait wrote, as to an epitaph on a tombstone, 'I want one thing recorded on it, and that to the effect that "he laboured to invert his profession from the blundering which has resulted from performance of experiments on the sub-human groups of animals in the hope that they would shed light on the aberrant biology of the human groups" (*Med. Press*, 1899, 118, 498). Surely the cruelty in any shape or form is reprehensible. Should it not be prohibited in the pursuit of remedial measures in medicine and surgery?

Her Tuberculosis?

G. B. LORD (Rushden, Northants) writes: "Striving to better, we may what's well"—*King Lear*, I, iv

Obituary

F. J. H. COUTTS, C.B., M.D.

Dr F. J. H. Coutts, who died at Bournemouth on the age of 83 on Feb. 13, was for many years a medical inspector of the old Local Government Board and senior medical officer of the Ministry of Health.

Francis James Henderson Coutts was born in Queensland, Australia, in 1865. He was the son of Robert Coutts of Wimmera, and received his medical education at Owens College, graduating M.B., Ch.B., with honours in pharmacology and therapeutics, in 1892, and proceeding M.D. in 1898, when he was awarded a gold medal for his thesis. He was a research fellow in pharmacology at Owens College and from 1899 to 1901 he was assistant to Professor Sheridan Delepine in the public health department of the university. Encouraged by Delepine, himself a pioneer in public health bacteriology, Coutts decided to make public health his life work. He took the D.P.H. in 1900 and the B.Sc. in public health in 1907. In 1901 he was appointed medical officer of health of Blackpool, where he soon became known as a capable and efficient administrator.

Sir Arthur Newsholme had become medical officer of the Local Government Board in 1908, and one of his first recommendations was that Dr Coutts should be a member of his staff. Coutts was duly appointed a medical inspector of the Board. His early work there was in the Foods Branch with Buchanan and MacFadden. He was a Fellow of the Chemical Society, and his wide knowledge of chemistry was utilized in investigations of the value of condensed and dried milks and proprietary foods in infant-feeding. In 1912, as the result of the Astor Report, a national tuberculosis service was set up under the Local Government Board, and Newsholme entrusted Coutts with the direction and planning of its medical administration. Coutts, as he often said, never pretended to expert knowledge of tuberculosis, but his public health experience and his reliance upon the clinical members of his staff enabled him to integrate the public health aspect with the curative side of tuberculosis work and to provide an excellent organization for the needs of the major local authorities which were responsible for tuberculosis schemes.

Coutts was an indefatigable writer of minutes, and during the early years of the national scheme worked long hours in Whitehall, often being the last official to leave the building. Newsholme found him an ideal coadjutor, and in 1915 entrusted him also with the medical planning and organization of the new venereal diseases scheme. The characteristic conscientiousness and ability that Coutts applied to this work was recognized outside official circles by his election as president of the Society for the Study of Venereal Diseases. All these important duties left Coutts little time for other work, but in 1915 a special report of his to the Board on anthrax due to infected shaving brushes imported from Japan led to the control and abolition of this method of infection.

The Ministry of Health was founded in 1919, and Coutts became senior medical officer in charge of tuberculosis and venereal diseases work. Throughout his official life he was a kind and considerate chief, and his integrity and justice inspired loyalty and confidence among his staff. In 1923 he was created a Companion of the Bath for his services. He examined in public health for Liverpool, Manchester, Birmingham, and Leeds Universities. He was a freemason, attaining to high rank in the craft. He also found time in his busy life for gardening and for golf. He was an enthusiastic motorist and a member of the Savage Club. In 1930 he retired and went to live at Bournemouth, where he was always glad to welcome his old friends and colleagues. He was a keen member of the British Medical Association and was one of the chief organizers of the successful annual meeting held at Bournemouth in 1934.

In 1937 some concern was expressed about the prevalence of tuberculosis in Wales and in September of that year Sir Kingsley Wood, the Minister of Health, appointed a committee consisting of Mr. Clement Davies, K.C., M.P., and Dr. Coutts to inquire into the anti-tuberculosis service in Wales and Monmouthshire. Their report, published in 1939, spoke highly of the official work of the Welsh National Memorial Association.

tion. The chief criticisms were directed to the preventive side of the work. The two-man committee did good service in stimulating co-ordination of the work of local authorities in Wales with that of the Association.

Towards the end of 1948 Dr. Coutts's health began to fail, and he died after a long illness. Dr. Coutts married Elizabeth Efford, daughter of Mr. C. G. Boullen, of Ambleside, in 1899. He is survived by his widow and two daughters.

C. H. ROGERSON, M.D., F.R.C.P.

Dr. Cuthbert Harry Rogerson, who died in Baltimore on Feb. 10 at the age of 37, was the medical director of the Seton Institute there. As a student at Guy's Hospital he was outstanding, and he won the Treasurer's gold medal for clinical medicine. He graduated M.B., B.S. in 1932, proceeded M.D. in 1933, and took the M.R.C.P. in 1934 and the D.P.M. two years later. Dr. Rogerson had been a house-physician and subsequently registrar in the department of psychological medicine at Guy's Hospital. At the end of this period he was awarded a Rockefeller fellowship and was able to spend a year with Dr. Adolf Meyer at the Johns Hopkins Hospital in Baltimore. He returned to Guy's as Sir Alfred Fripp fellow, and he was later psychotherapist at the Hill End Hospital, St. Albans. During this period he interested himself particularly in the psychiatric problems of young children. In 1937 he was appointed medical director of the Cassell Hospital at Panshurst. There he proved himself a capable administrator, and he wrote at this time a number of papers on play therapy in childhood, psychological factors in asthma, prurigo, and on the differentiation of neurosis and psychosis. In 1945 he was elected F.R.C.P.

Dr. Rogerson had already achieved much in his special field, and the opportunity for further achievement came in March, 1946, when he settled in Baltimore as director of the Seton Psychiatric Institute. He looked forward to the task of reorganizing the Institute, and he soon built up a staff of keen young men. He began teaching postgraduate students, and he renewed his old association with the Johns Hopkins Hospital. It seemed that he was safely embarked on a career that promised great distinction, and then about a year ago he fell ill.

B.A. writes: The news of Dr. Rogerson's death has not come as a shock to his many friends in this country, as for many months they had known the inevitable end. I leave it to others to give an account of his high professional qualities and achievements: his death is a great loss to British and American psychiatry. I want only to talk about the colleague and friend with whom I was closely connected for five years—war years, with strain, stress, and gross overwork, a time apt to bring out the best or the worst in people. In Dr. Rogerson it brought out the best. He was a man filled with human kindness, full of genuine and sincere interest in people, always ready to help by word and deed, a man with a deep understanding of human weaknesses who never had a bad word to say of anybody. He combined great modesty with quiet self-assurance, an inexhaustible thirst for knowledge, and an infinite capacity for work that made him the successful research worker he was. He had a great sense of humour which never deserted him, made difficulties less difficult, and added to the charm of his company. He had the rare gift of bringing out the best in with whom he worked. Not only his colleagues but the entire staff felt the human interest he brought to bear in all their joys and sorrows. His harmonious personality pervaded the whole hospital and made it a happy place. He was an excellent conversationalist. His interests were not confined to medicine; he was at home in art and literature, especially in poetry. There was hardly a topic, however remote from the commonplace, to which he could not contribute in his own inimitable way. He was very popular and will be missed by many, but for his friends the world has become a poorer place without him.

Dr. FRDERICK RITCHIE SINTON died on Dec. 8, 1948, following a motor crash in which his brother also lost his life. He was born in 1882, and graduated M.B., Ch.B. at Edinburgh in 1904. After a short assistantship at Goole he came to Leeds in 1908 and started practice in Woodhouse, where he lived and worked until his untimely death. He served on the R.A.M.C. from 1915 to 1917, for much of this time in Salonika. He was a Conservative member of the Leeds City Council from 1920 to 1924; a member of the Leeds Panel Committee for many

years; carrying out the arduous duties of chairman from 1939 to 1946; and he was also a member of the Leeds War Emergency Committee. He was keenly interested in medical politics and opposed the precipitancy with which the present National Health Service was introduced. Dr. Sinton was an enthusiastic supporter of all outdoor sports, and particularly of the Headingley Rugby Football Club, of which at one time his elder son was captain. In his early days he was keen on boxing. He was a sound and progressive general practitioner, held in high esteem by his colleagues. He had a genial presence, with twinkling eyes and a ready, infectious laugh, and with his generous and sympathetic nature he endeared himself to his patients, fellow practitioners, and friends. Although in his later years Dr. Sinton suffered many serious illnesses which might well have daunted a lesser man, he always faced the future with high courage. He never lost his zest for life but carried on smiling and cheerful to the end. His wife, whom he married in 1906, died a year ago, and he is survived by two sons, the elder carrying on the practice and the younger being the Leeds City police surgeon.

Dr. JOHN GRIMSON MOSELEY, one of the best-known practitioners in Jamaica, died on Jan. 11 at the age of 62. Dr. Moseley, who was a student at the London Hospital, took the conjoint diploma in 1911. He then went back to Jamaica and was in practice with his father, the late Dr. C. A. Moseley of Port Antonio, until 1914. During the 1914–18 war he served in the R.A.M.C. with the rank of major, and after demobilization he graduated M.B., B.S., and proceeded M.D. in 1920. He rejoined his father for a short time, and subsequently settled in Kingston, where he did a great deal of work for the Nuttal Memorial Hospital and St. Joseph's Sanatorium. In the recent war he acted as surgeon-specialist to the Up-Park Camp until 1943, when he was appointed medical superintendent of the United Fruit Company.

H.A.L. writes: I knew Moseley intimately while we served together in the same units in the first world war. Straight as a gun-barrel, Moseley had a mind of his own, but was delightfully easy to get on with, a charming and intelligent companion with a common-sense outlook on life, and he appeared to me to have a deep knowledge of medicine. After the war he returned to Jamaica so that I saw nothing of him until I had the pleasure of a visit at the end of last year. He was tired, and said that he was glad that the time of his retirement from practice was at hand.

Dr. ALEXANDER MCCONNELL ERSKINE died in a nursing-home at Harrogate on Jan. 21 at the age of 80. He had been medical officer of health for Goole for forty-four years, retiring only two years ago. Dr. Erskine was born in Ulster, and graduated at Belfast University in 1889, proceeding M.D. in 1904. Two years previously he had been appointed medical officer of health for Goole at a time when the death rate was high and the infantile mortality rate was 188 per 1,000 births. Dr. Erskine saw the first child-welfare centre opened in the town in 1915, and this was followed by a maternity home in 1926, and in 1938 by the new health centre. He stressed the need for a cheap or free supply of milk to babies and infants more than forty years ago. He was also an early advocate of immunization against diphtheria, and was proud of the fact that since 1943 there had been no deaths from diphtheria in Goole. Dr. Erskine married Miss Dora Stanners Blair, daughter of Dr. Robert Blair, who survives him, and to whom the sympathy of all his friends and colleagues will be extended.

E.C. writes: Dr. Erskine had a real love and understanding of children and remained young in spirit up to the last. He was keenly interested in music, of which he had knowledge to enable him to appreciate it at its true worth, and he was widely read. In 1935 he was one of those who did the B.M.A. world tour and enjoyed it to the full, attending the annual meeting at Melbourne and making friends both on the voyage and in Australia. On the morning of Jan. 5, accompanied by his wife, he visited the isolation hospital, of which he was medical superintendent, and paid several other visits, driving his car with his usual ease and enjoyment. During the afternoon he suffered a coronary thrombosis, and until the day of his death on Jan. 21 he bore much suffering with fortitude and even with unflinching humour. His dignified and upright figure and his genial and lovable personality will be greatly missed by patients, colleagues, and a wide circle of friends.

In our obituary notice of Dr. F. H. A. Marshall (Feb. 12, p. 287) there was a reference to the third edition of his book *The Physiology of Reproduction*, which was first published in 1910. The publishers inform us that the third edition has not yet appeared, but publication is expected next year.

Medico-Legal

BREACH OF TERMS OF SERVICE

The Executive Council for the City of Sheffield unanimously approved on Feb 1 a report from the Medical Service Committee recommending that the sum of 150 guineas should be withheld from the remuneration of a medical practitioner.

This case arose out of the attendance at the surgery of a practitioner on the Council's medical list on Nov 9, 1948, of an insured woman who claimed treatment as a National Health Service patient. The practitioner was unable to trace her name in his records and he charged the patient a fee for which he issued a receipt. On Nov 10 the patient attended at the offices of the Executive Council to apply for a refund of the amount paid by her to the doctor, when she produced three medical certificates—a "first" certificate dated Nov 9, an "intermediate" certificate dated Nov 16 both signed by the practitioner, and a "final" certificate which was undated and unsigned. The issue of these three certificates appeared to disclose an irregularity and they were accordingly retained at the offices of the Council. On the same date, Nov 10 the patient signed a statement to the effect that all three certificates had been given to her by the practitioner at the same time, with instructions that they should be sent in the correct order to the Ministry of National Insurance.

The clerk of the Council communicated the details of the case to the district officer of the Ministry of National Insurance in order that the patient's claim to benefit under the National Insurance Act might not be prejudiced, and on Nov 11 he forwarded the three medical certificates, together with a copy of the patient's signed statement to the Ministry of Health in accordance with the provisions of Regulation 13(i) of the National Health Service (Service Committees and Tribunal) Regulations, 1948, for such action as the Minister deemed necessary.

In a letter dated Nov 22 the Ministry of Health stated the view of the Minister that the matter was one which ought to be investigated by the Medical Service Committee, since there appeared to be a *prima facie* case that the doctor had failed to comply with his terms of service. Clause 7(7) of Part I of the First Schedule to the National Health Service (General Medical and Pharmaceutical Services) Regulations, 1948 made it obligatory for a practitioner, in issuing medical certificates, to comply with any regulations made under the National Insurance Acts, 1946 and the National Insurance (Medical Certification) Regulations, 1948, were thus incorporated in the doctor's terms of service. Clause 2(b) of Part I of the Schedule to these regulations stated that every certificate should contain the date of the examination on which the certificate was based, and also Clause 4 stated that every certificate must have been given on a date not more than one day later than the date of the examination on which it was based and no further certificate based on the same examination should be furnished other than a certificate to replace an original certificate which had been lost or mislaid.

On Dec 7 the matter was considered by the Executive Council who decided, in accordance with Regulation 4(5) of the National Health Service (Service Committees and Tribunal) Regulations, 1948 to refer the case for investigation by the Medical Service Committee. On Dec 8 the clerk informed the practitioner of the Council's decision, and in a reply dated Dec 9 the practitioner stated he was still attending the patient. The certificate dated Nov 16 had been issued in the knowledge that he would attend her on that date and on that date he had visited her.

Subsequently the patient submitted to the Ministry of National Insurance three further intermediate certificates dated respectively Nov 23, Nov 30, and Dec 7, 1948 and in a statement to an officer of that Ministry on Dec 14 she stated she had attended the practitioner's surgery on Nov 9, when the practitioner had issued three medical certificates which she had taken to the offices of the Executive Council. The practitioner had visited her on Nov 23 and on each subsequent Tuesday. She had not sent for him, but he had visited her as arranged on the occasion of her surgery attendance.

Medical Service Committee Hearing

The practitioner was present at the hearing by the Medical Service Committee, as also were a member of the staff of the Executive Council and an officer of the Ministry of National Insurance. The patient did not attend. The practitioner stated that the patient had attended his surgery on Nov 9, when he issued a first certificate, and as the patient appeared to be in ignorance of the correct procedure he explained that she needed a certificate each week. He gave her an intermediate certificate dated Nov 16, and a final certificate which he had neither signed nor dated. The doctor stated he had not intended to sign the certificate dated Nov 16, but had done so inadvertently as he was trying to explain to his patient that she must have a certificate each week. He added it was not uncommon to give certificates in serious illnesses several at a time and to sign them later, when they became due. Such certificates could be signed on the occasion of a visit to the patient's home. The practitioner understood this was a technical breach of the Regulations, but he added that if a practitioner could not trust a patient to the extent of giving him a certificate form when he was seriously ill, and filling it up on the occasion of a subsequent visit, he thought the doctor had a very poor working arrangement with his patient. He frequently gave patients blank certificates which were to be presented to him for signature at later dates. The practitioner agreed that all the statements contained in the patient's statement of Nov 10 were correct.

In reply to a question the practitioner stated he saw the patient for the second time when he visited her, at her own home, on Nov 16. He was then asked if he could explain the patient's statement that he had visited her on Nov 23—no mention having been made of any visit on Nov 16—but to this the doctor made no reply. When asked if he had any evidence of his visit to the patient on Nov 16, he said he had a visiting card for her.

A member of the staff of the Executive Council stated that the patient had presented the three certificates in question to him as an officer of the Council, and had asked for the address of the Ministry of National Insurance to which they should be sent. He had then stamped the certificates with his personal stamp, showing that they had been received in the Council's office on Nov 10, 1948, and the patient had then voluntarily made the statement bearing that date. An officer of the Ministry of National Insurance stated that he had visited the patient, who in a freely given statement said the doctor had visited her on Nov 23. She had made no reference to Nov 16, and the officer, who had not asked for any specific dates, formed the opinion that the doctor had not seen the patient between Nov 9 and Nov 23, 1948. The member of the Council's staff here recalled, stated he had visited the patient, in the company of a colleague, on Dec 16, and in the course of questions on specific points he had asked her whether, definitely, the doctor had visited her on Nov 16, to which she had replied in the negative.

The practitioner then stated that when he visited the woman on Nov 16 she was in bed. He had to visit her home, but he did not get to see her because there was no one there. He understood the patient was in bed, as nobody answered the door, and he was told she was in bed. The date of his next visit was Nov 23, when he was able to see her. The doctor again admitted that on Nov 9 he had issued a certificate dated Nov 16.

Findings

The Committee found that the practitioner's action in issuing a post-dated intermediate certificate on Form Med 2A and an unsigned, undated final certificate on Form Med 2B, as admitted by him constituted a breach of Clause 2(b) and Clause 4 of Part I of the Schedule to the National Insurance (Medical Certification) Regulations, 1948, which are incorporated in the doctor's terms of service. The Committee feel strongly that this action of the practitioner's which was quite indefensible, was an extremely serious matter which indicated that no reliance could be placed upon his certificates. If the procedure used by this practitioner in the issue of medical certificates were adopted by other doctors it would soon become impossible to administer the National Insurance Act. The Committee feel that the integrity of the medical profession should be protected against such actions.

In considering the recommendations to be made to the Executive Council the Committee took into account the practitioner's attitude in this case, and also the fact that he had only recently appeared before them in connexion with another serious matter, when a warning had been issued to him that he exercise more care in his observance of the terms of service. The Committee accordingly recommended: (i) that a warning be issued to the practitioner that, in the event of his again being summoned to appear before the Committee in connexion with a serious breach of his terms of service, the Council would consider whether to exercise their right, under Regulation 6(d) of Part II of the National Health Service (Service Committees and Tribunal) Regulations, 1948, to make representations to the Tribunal that the continued inclusion of the practitioner on the medical list would be prejudicial to the efficiency of the service; and (ii) that the Council make representations to the Minister that, owing to the failure of the practitioner to comply with the terms of service, the sum of one hundred and fifty guineas be withheld from his remuneration.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

In a Congregation held on Feb. 5 the following medical degrees were conferred:

M.D.—J. A. Glover.
M.B., B.Chir.—*R. B. McGregor, *J. W. MacLeod, *F. D. Schofield, *P. J. Andrew, *J. G. Gill, *J. Halford, *J. C. Burne, *Margaret L. Cox

* By proxy

UNIVERSITY OF LONDON

The governing body of the British Postgraduate Medical Federation has approved the award of Postgraduate Travelling Fellowships for 1949-50, tenable for one year, to Mr. J. V. Crawford, of the London Hospital (Neurosurgery, U.S.A.); Dr. J. S. Prichard, of the National Hospital, Queen Square, and the Postgraduate Medical School, Hammersmith (Neurology, U.S.A. and Canada); Dr. R. D. Tonkin, of Westminster Hospital (General Medicine, U.S.A. and Canada); and Dr. J. E. M. Whitehead, of St. Thomas's Hospital (Bacteriology, Scandinavia).

UNIVERSITY OF LEEDS

At a meeting of the Council of the University held on Feb. 16 Wallace Ironside, M.B., Ch.B., D.P.M., was appointed Senior Lecturer in Psychiatry.

Dr. John Jamieson and Miss Jamieson donated £100 for the endowment of a Prize in Practical Anatomy in memory of their father, the late Professor J. Kay Jamieson.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on Feb. 10, with Lord Webb-Johnson, President, in the chair, the appointment of Mr. V. Zachary Cope as Bradshaw Lecturer was announced.

Mr. Julian Taylor (University College Hospital) was re-elected and Mr. T. A. Hindmarsh (Newcastle), Mr. R. J. McNeill (Love Royal Northern), and Mr. Digby Chamberlain (Leeds) were elected members of the Court of Examiners.

Mr. J. S. Arkle (Newcastle) and Mr. F. C. Hunt (Nottingham) were elected to the Fellowship of the College *ad eundem*.

Sir Henric Ogilvie and Mr. L. C. E. Norbury were reappointed as the representatives of the College on the Council of the Imperial Cancer Research Fund, and Mr. J. M. Wyatt was re-elected as representative on the Central Midwives Board.

The Hallett Prize was awarded to I. S. R. Sinclair, of the University of Edinburgh.

The Diploma of M.R.C.S. was granted to C. P. Cotterill and to the 134 successful candidates whose names were printed in the report of the meeting of the Royal College of Physicians of London in the *Journal* of Feb. 5 (p. 249) as recipients of the diploma of L.R.C.P.

Diplomas in Public Health (twenty-two), Laryngology and Otology (five), Psychological Medicine (one), and Anaesthetics (two) were granted jointly with the Royal College of Physicians of London to the successful candidates whose names were published in the report of the meeting of the Royal College of Physicians of London in the issue of Feb. 5 (p. 249).

The following hospitals were recognized under paragraph 23 of the F.R.C.S. regulations: Mount Vernon Hospital and Radium Institute, Northwood (surgical registrar, first, second, and third, and house-surgeons); Hillingdon Hospital, Uxbridge (surgical registrar and senior house-surgeon).

Medical Notes in Parliament

COST OF HEALTH SERVICE

Supplementary Estimate Approved

On Feb. 17 the House of Commons went into Committee on Supply to consider the supplementary estimate of £52,800,000 for the National Health Service in England and Wales.

Mr. BLENKINSOP, Parliamentary Secretary to the Minister of Health, said that the supplementary estimates were of a very large size and therefore warranted close inspection by the committee. The estimates were introduced some seven months before the introduction of the scheme. It was quite impossible to tell the extent to which the new scheme would be used by the general public. It was impossible to tell just how far the professional services would be available. A factor of great importance which again could not be evaluated at that time was what would be the remuneration of those taking part. At the head of the estimates would be seen provisions for hospital services. That covered the figures of advances both to regional hospital boards and to boards of governors of teaching hospitals. The additional sum was £22,346,000. The Service covered over 36,000 hospitals and clinics together with some 36 teaching hospitals. There had been £3,500,000 additional capital expenditure.

The major cause of the increased running expenses was increased pay of staff. The pay of student nurses had been almost doubled at a cost of some £3,000,000 a year, including improvements in other nurses' pay that amounted to an extra charge of £1,500,000. The increased pay of domestic workers in hospitals amounted to £2,000,000 a year, of which £750,000 was involved in the period of the estimate. Other staff increase amounted to about £1,500,000 a year, and special provisions had been made for increases to doctors and specialists in hospital as a result of the Spens Report, for which provision had been made by some £6,000,000. This might not be the end of the wage increases which might be needed in the professorial negotiations were proceeding at the moment.

Although provision was made for an extra £16,000,000 for liabilities transferred to the Minister, a large part of that would be recouped from the Hospital Endowments Fund. There was no intention to raid the fund. There would be a set-off one against the other, but they had no intention of depriving the fund at all. An extra sum of £370,000 was for increased payment to the Ministry of Pensions. It covered the provision of artificial arms and legs, and artificial aids of most kinds, including surgical boots, motor- and hand-propelled chairs, and artificial eyes.

There had been another large increase in the amount required for grants made to local authorities. Many of those services did not in the past attract any Government grant at all. To-day all of them attracted a 50% Government grant. Such services included care of mothers and young children, home helps, home nursing, and ambulance services. There was provision for an extra £716,000 for the expenses of administration. It had been found necessary to increase staffs to enable the work to be efficiently carried out. Some part of that expenditure was non-recurrent. Provision was also included for an extra £500,000 which had been added to the Mileage Fund for doctors in rural areas.

An addition of nearly £5,000,000 was required for the pharmaceutical service. The estimates were based on the old N.H.I. scheme, under which some 50,000,000 prescriptions had been issued in an average nine-monthly period. Provision had been made for an increase of a little over double that number of prescriptions. In fact something like 128,000,000 prescriptions would be needed in that period of nine months. The cost of the actual individual prescriptions had been greatly increased over the estimate. There had been payments to chemists in advance of the normal dates which merely represented transfer from one period to another. There was no evidence of any general misuse of prescribing by the medical profession. There might undoubtedly be individual cases, but full provision existed for keeping watch on that matter.

The estimates for the dental service—just under £12,000,000 increase—had been originally prepared before the Spens Report had been received. The increase for the ophthalmic services amounted to about £11,000,000. Under the N.H.I. scheme only 5% of those entitled to benefit had made use of the provision. The demand had been increased to some four times the previous estimate. Up to Jan. 31 nearly two million pairs of spectacles had been provided. They were not saying that either on the dental or on the ophthalmic side they were satisfied with the rates of payment to those who were participating, and discussions were proceeding on that matter which would no doubt assist in future periods.

They were a bulwark against the fears of insecurity in the past and to that extent were an encouragement to the economic effort and the difficult period which lay ahead

Wrung from the Taxpayer

Mr. ASSHETON said that anyone who understood our financial position and had paid heed to the remarks of the Chancellor of the Exchequer in recent months must have been deeply shocked and alarmed by the introduction of a batch of supplementary estimates which represented in total practically all the money that was being wrung from the taxpayer by way of purchase tax

Members of the Opposition who were in the Coalition Government and had had a hand in framing the post war social services were feeling very great anxieties lest all the hard work should be brought to naught by the shocking administration of the Minister. In the declaration of policy which the Conservative Party had put to the electorate the intention had been laid down clearly to provide a comprehensive health service, and that had always been their policy. They should not overlook the fact that it was from the pockets of the working men and women that the greatest contribution came

He wished to criticize first the childish underestimation in respect of which there had been no satisfactory explanation by the Parliamentary Secretary. He wanted to comment on the obvious growth of bureaucracy which these estimates showed. The National Health Service Bill was introduced on March 19, 1946. The final figure of the financial memorandum was "The net annual expenditure falling upon the Exchequer is £95,000,000". The estimate introduced by the Minister last spring was £132,000,000. He had now come along with an additional supplementary estimate for £52,000,000. Those figures for the estimate and for the supplementary estimate covered only nine months.

The matter of the ophthalmic service was very puzzling. The original estimate was about £2,000,000, the revised estimate was for £12,500,000—an error of estimation of 600 or 700%. Plenty of other people had known that the service would cost more than £2,000,000. The cost of a pair of spectacles was from £2 18s to £3 14s. Before the scheme came in there were about four million pairs made in England every year. Somebody might have guessed that the cost might be four million times £3. That would have given an estimate of £12,000,000.

Sir ROBERT YOUNG asked whether he was taking account of the number of spectacles exported in that four million.

Mr. ASSHETON did not believe that many had been exported and the Minister had said that more than two million pairs had been supplied by his Department.

On the general practitioner estimates, it was clear that the amount spent on one or two services alone this year exceeded the total amount spent on family doctoring. Critics had suggested that that disclosed a lack of proportion. He suggested that doctors up and down the country were in many cases over-worked and had not sufficient time to give attention to their more urgent cases. In some country districts doctors were badly hit financially while they saw around them enormous and wasteful extravagance which wise administration might avoid.

The teaching hospitals were to have had £10,000,000 and now wanted £18,000,000 and regional hospitals, which were to have had £91,000,000, were now up to £103,000,000. How could such estimating be excused? He had been told that the administration of hospitals had in many cases been removed from the hospital itself, that a great bureaucracy was growing up. There was great over-centralization of administration. The public had been deceived into thinking that there were far more services available than in fact there were. The Minister had shown himself quite irresponsible in financial matters and heedless of the best interests of the patients as well as of the medical profession. Mr. Assheton suggested that he was unfit to hold office and should go.

Extent of Need Shown

Mr. MESSER said that the supplementary estimate indicated the extent of the need for the Service. Did the Opposition suggest that, because the number of people who would benefit by an expensive drug like streptomycin was unknown, tuberculous people should die because the estimate was wrong? If that was the position the debate would be the finest ammunition for the general election there had ever been. The supplementary estimates could be justified on the grounds that human life was more important than cash.

Sir HUGH LUCAS-TOOTH suggested that the Minister was not only guilty of bad estimating but guilty of reckless under-statement. The policy of the Minister had been to keep the estimates as low as possible so that the scheme would be on its feet and the House would be presented with a *fait accompli* in the supplementary estimates.

Miss BACON said that there were various groups in the country at present who were asking for more money. They might have a good case, but it was noticeable that in recent months the Tories had been encouraging those pressure groups to ask for more services of one kind or another. How did the Opposition reconcile that attitude with their present one?

Colonel STODART-SCOTT asked the Minister to say what step he was taking to prevent abuse of the dental scheme. Why was £11,000,000 extra wanted for the ophthalmic service? The Minister had built up an over-centralized administration. He had collected many new people who had had no experience of administering hospitals. He had shown a great unwillingness to accept advice, or take advice, or even seek advice.

Mr. W. GRIFFITHS said he did not think there was any substantial frivolous demand for the ophthalmic service.

Mr. H. LYNSTED said there was unnecessary competition between hospital groups in the matter of hospital salaries and wages of staff. He hoped that the Minister would leave the professions, regional boards, and management committees the greatest amount of liberty to put their enthusiasm into doing their job with the very minimum of central control.

Mr. FERNYHOUGH said that if there was extravagance it was a reflection upon the members of the medical and dental professions, because they were the people in whom the Minister must have complete trust. The people had given the scheme a welcome which augured well for the Labour Party's prosperity at the next election.

Sir HENRY MORRIS-JONES said that he had had a letter from a working man in a London hospital in which there was an analysis of the money being spent on the administrative sector of the hospital at the expense of the efficiency and equipment of the staff.

Mr. BEVAN said that if a charge was being made that a hospital was being extravagant, it was the honourable Member's public duty to give its name.

Sir HENRY MORRIS-JONES said that he would be informed of the name in due time. It was no wonder that Sir Frederick Menzies had stated on Dec. 11 [in a letter in the *Supplement* Dec. 11 1948, p. 220] that if some drastic steps to reduce hospital costs were not immediately taken those enormous costs might have serious repercussions on the medical services other than hospital work.

Mr. BEVAN asked if the salaries should be reduced.

Sir HENRY MORRIS-JONES said that he suggested nothing of the kind.

Dr. HADEN GUEST said that they should not lay too much emphasis at present on the building of new and expensive buildings for health centres. Rather they should spend their energies on building up teams of doctors. The difficulty was not to get doctors into buildings but to get groups of doctors to work together. He would like to mention that this week in the medical press—in one article in the *British Medical Journal* and another in the *Lancet*—there were reports of staggering progress in medical work. In the *British Medical Journal* there was the account of a series of 5,000 childbirth deliveries without one maternal death. In the *Lancet* there was a description of a new discovery for treatment of Parkinson's disease.

Mr. DAVID ECCLES asked whether they could not cut down some of the waste and get the same services for less with better administration. When the Opposition was accused of not wanting the health services that was not true. They were anxious that the maximum amount of money devoted to the civil estimates should be divided in the best way.

Dr. SANTO JEGGER said that the Opposition talked about cost as being the most important factor. He disapproved of that attitude and condemned it. The Labour Party's attitude to life was not based on money, but that of the Opposition was almost entirely monetary.

Mr. W. E. ELLIOT said that the Opposition had been accused of being careless or of hostile to, improvement in the health of the people. They were perfectly willing to put their record against the record of any other party. Great sections of hospital accommodation were closed because they could not be staffed. The Minister asked for £180,000,000. How many more beds did he expect to open? That was the acid test.

The real danger was that a consolidation of our expenditure at a level away above the level before the war might take place. If the cost-of-living figures were established at something like 95%, or still worse at 300%, as in the case of building, above pre-war the shock to the economy of the country would be profound.

Mr. Bevan's Reply

Mr. BEVAN, after protesting against the absence of Mr. Churchill, said that it had been hard to find out what the Opposition were complaining about. Were they saying that it would have been all right to spend this money in this way if it had gone in the original estimate, or did they object to spending

the money at all? The Parliamentary Secretary did not refer in his speech to the fact that, when they put in the estimate seven months before the money started to be spent he (Mr Bevan) had still been in negotiations with practically all the professions—chemists, dentists, ophthalmic opticians, and the B.M.A.—negotiations with whom had not then ceased. Further, the Spens Committee on specialists' remuneration had not reported. How was he to know at that stage what would be the outcome of these negotiations?

When Ministers were in negotiation with sections of the community it was a very serious matter if a Minister in the middle of those negotiations was subjected to pressure lobbies and log-rolling by the sections concerned. He was engaged, or should be engaged, in defending the public interest against the sectional interest with which he was negotiating.

The fact was that he considered without, he thought, much immodesty that the launching of the National Health Service had been one of the greatest pieces of civil administration in the history of all civil government in peacetime. One of the reasons why the Opposition was now running away was because they had already found out that what Mr Churchill said last Thursday was almost as unpopular among Conservatives as among Socialists.

In future they would have a global budget determined by the regional hospital boards and the management committees of hospitals. Within those global budgets the management committees would have discretion to spend what they wished on this or that item of administration. If they spent more on one they spent less on another. They were trying to work out a system of resilient administration with as little bureaucracy as possible, with as much local self-government as possible, and would at the same time protect the public purse against extravagant administration. They would show the world how they could centralize financial responsibility and decentralize day-to-day administration in a great service of that sort.

The voluntary hospital system had been financially failing. The amount of money they were finding to keep the voluntary hospitals vastly exceeded all the money in their Endowment Fund. It was obviously impossible to know to what extent spectacles and dental operations would be required. How did they know what was going to be the demand?

Whenever they had been able to relieve in any way the burden of suffering of the people of Great Britain the burden had always proved to be heavier than they ever thought it would be. Past conditions concealed a vast amount of inarticulate misery and pain. In so far as those figures represented relief of genuine need everybody ought to be proud of them, but if there was abuse let them co-operate in getting rid of it.

The Service had not been launched in harmonious circumstances, in fact no medical service in the world had ever been launched in harmonious circumstances. Who would have thought that they would have in the Service many more general practitioners than the Government had thought would come in? Who would have suspected that 95% of the population would have registered with general practitioners by the end of the year? Although the financial burden was great they must set off against it the enormous sum of misery already alleviated.

Why did not the honourable and right honourable gentlemen opposite start ceasing to be sour? The Tory Party used to represent itself as a jocund party. However, that had all gone now—pale and miserable lot. Every increase in the health, buoyancy, and vitality of the nation—instead of welcoming it they groaned at it. They hated it because they thought it spelt electoral defeat.

It was necessary that the money be not spent upon the most articulate members of the community, who might be the chemists, the doctors, the dentists, or the ophthalmic opticians. It might be even the health workers because each one of these sections was highly organized and able to bring pressure to bear upon Parliament and upon Ministers. He was anxious that the money be not spent on the persons who could organize themselves into loud pressure lobbies and get their columns in the Press, but on the patients who had to make use of the Service. He welcomed the discussion which had taken place. It had shown the hypocrisy of the Opposition and it had shown the soundness of the Service.

The estimate of a supplementary sum not exceeding £52,800,000 was agreed to without division.

The Raw Opium Regulations, 1948, and the Dangerous Drugs Regulations, 1948, which came into effect on Jan. 1, include amidone and pethidine among those drugs of which a separate register or part of a register must be kept. They specify the preparations of opium which practising midwives may obtain on their own authority, and extend to registered veterinary practitioners the same authority in respect of the possession and supply of dangerous drugs as a registered veterinary surgeon has.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Feb. 1.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland. Figures of Births and Deaths, and of Deaths, recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases a blank space denotes disease not notifiable or no return available.

Disease	1949					1948 (Corresponding Week)

Deaths (excluding stillbirths) Annual death rate (per 1,000 persons living)	5,957	1063	780	205	132	5,191	844	685	224	148
Live births Annual rate per 1,000 persons living	7,292	1108	906	394	208	7,999	1320	954	418	280
Stillbirths Rate per 1,000 total births (including stillborn)	19	24	25	—	—	24	21	25	—	—

* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county) will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county) are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Influenza

In the 126 great towns in the week ended Feb. 12 there were 94 deaths from influenza compared with 64 in the previous week. This figure is higher than that for the corresponding week of 1938, 1942, 1944, and 1948, but lower than the corresponding week of 1939, 1940, 1941, 1943, 1946, and 1947. There have been no definite reports of new outbreaks, but there have been many indefinite reports of a high incidence of upper respiratory disease in certain places.

There is an increased incidence of influenza in Northern Spain but no increase in general mortality there. There has also been an outbreak in the American zone of Germany, in South-west Bavaria, chiefly affecting school-children.

News has been received from Dr. Burnet, of Melbourne, that a strain of virus A recently recovered from the Ocean Islands is identical with the current European strain. All strains fully investigated by the World Influenza Centre, from this country and from the Continent in the first six weeks of this year, are identical.

Discussion of Table

In *England and Wales* infectious diseases were more prevalent during the week, and there were increases in the notifications of measles 2,144, whooping-cough 311, scarlet fever 181, acute pneumonia 81, and dysentery 15. There was a decrease in the incidence of diphtheria 25.

The largest increases in the notifications of measles were Yorkshire West Riding 422, Essex 316, Staffordshire 198, and Devonshire 154; the decline in Lancashire continued, and a fall of 189 was recorded. There was a small rise in the notifications of scarlet fever in every region except the south-western and eastern, where small decreases occurred.

The largest rises in the incidence of whooping-cough were Kent 66, Yorkshire West Riding 46, and Warwickshire 43. The decline in the notifications of diphtheria was mainly due to the experience of Lancashire, where the notifications fell from 39 to 19.

The increased incidence of dysentery was also contributed by Lancashire, where an increase of 26 was recorded. The chief centres of infection in this county were Blackpool C.B. 20; Liverpool C.B. 10; and Whiston R.D. 7. Notifications of acute poliomyelitis were 11 fewer than in the preceding week, and 3 of the 9 cases were notified in Gloucestershire, Bristol C.B.

In *Scotland* there were decreases in the notifications of whooping-cough 52, scarlet fever 39, and acute primary pneumonia 37; the only increase of any size was measles 34. Of the 22 cases of dysentery 13 were notified in the city of Edinburgh.

In *Eire* there were decreases in the notifications of whooping-cough 23 and measles 18. A decrease of 9 in the notifications of diarrhoea and enteritis was reported from Dublin C.B., but this was offset by an increase of 10 in the remainder of the country.

In *Northern Ireland* infectious diseases were more prevalent than in the preceding week, and increases were recorded for measles 39, whooping-cough 20, and scarlet fever 15. The largest increases in the incidence of measles were Belfast C.B. 37 and Antrim County 20. An increased incidence of whooping-cough and scarlet fever was general throughout the country.

Week Ending February 12

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,417, whooping-cough 3,011, diphtheria 148, measles 18,441, acute pneumonia 1,139, cerebrospinal fever 30, acute poliomyelitis 15, dysentery 68, paratyphoid 5, and typhoid 7. Deaths from influenza in the great towns numbered 94.

The first part of an exchange visit arranged by the British Council and the Polish Government began on Jan. 30 when a group of five Polish medical professors came to meet leading members of the British medical profession and visit hospitals and universities. In March a similar group from Britain will go to Poland as the guests of the Polish Government. The visitors are Professor Anton Dobrzanski, Professor of Laryngology and Dean of the Medical Faculty, University of Warsaw; Professor Adam Grucza, Professor of Orthopaedic Surgery, University of Warsaw; Professor K. Jonscher, Professor of Paediatrics, Poznan University; Dr. Tadeusz Kielanowski, Dean of the Faculty of Medicine, Marie Curie University, Lublin; and Professor Semerau Siemianowski, Professor of Internal Medicine, Warsaw University.

Medical News

Medical Fellowships and Fellowships in Chronic Rheumatism

In the advertisement pages of this week's *Journal* the Nuffield Foundation invites applications for medical fellowships and for fellowships in chronic rheumatism. The closing date for receipt of applications is April 1. Full particulars can be obtained from the secretary of the Foundation, 12 and 13, Mecklenburgh Square, London, W.C.1.

Committee on Carcinogenic Action of Mineral Oils

The Medical Research Council has appointed the following to advise and assist them in the prosecution of research on the carcinogenic action of mineral oils: Professor T. Ferguson (chairman); Colonel S. J. M. Auld, D.Sc.; Professor J. W. Cook, D.Sc., F.R.S.; Professor A. Haddow; Dr. J. O. Irwin, D.Sc.; Professor J. R. Squire; Dr. D. L. Woodhouse, Ph.D.; Dr. J. M. Rogan (secretary). In addition the Ministries of Fuel and Power, of Health, and of Labour and National Service have nominated representatives who will attend meetings when matters of interest to these departments are likely to arise.

City of London School Register

A comprehensive register, with biographical details, from 1837 to the present time, of all masters and pupils of the City of London School is being prepared for publication. All former pupils are asked to apply to the editor of the register, City of London School, Victoria Embankment, E.C.4, for a form of questionnaire. The late Dr. Ernest Hart, a former editor of the *Journal*, was captain of the school in 1851-2.

Dental Technicians' Associations to Amalgamate

The Denture Service Association and the United Dental Technicians Association have decided to amalgamate "with a view to the establishment as soon as practicable of independent status for dental technicians analogous to that already enjoyed by ophthalmic opticians." They have decided to oppose the Bill for regulating the craft of dental technicians.

Oliver Memorial Fund

The committee of the Oliver Memorial Fund intends to make the second award of the value of £50 to a British subject whose original work or service in connexion with blood transfusion is considered to be a notable contribution to the research, organization, or donor aspect of this subject. The committee will welcome applications and, in addition, communications drawing its attention to suitable candidates. All correspondence should be addressed to the honorary treasurer, F. W. Mills, Esq., National Provincial Bank, Ltd., Holborn Circus, London, E.C.1, to whom applications must be submitted by June 30.

Russia Leaves WHO

Soviet Russia, the Ukraine, and Byelorussia have cabled to the executive secretary their withdrawal from the World Health Organization. Their decision is stated to be based on dissatisfaction with the organization's work and the expense involved; its "swollen administrative machinery" is "too heavy for member States to bear." Dr. Brock Chisholm, the executive secretary, has replied, according to *The Times* of Feb. 17, that the telegrams have been received with regret, but that he cannot accept the resignations, for which the constitution of WHO makes no provision.

Beryllium Poisoning

Beryllium poisoning has been added to the list of industrial diseases prescribed under the National Insurance (Industrial Injuries) Act. An employed person who contracts it may claim industrial injury or disablement benefit. In a fatal case death benefit may be paid.

New Medical M.P.

Dr. A. D. D. Broughton, who won the recent by-election at Batley, has been in general practice at Batley since 1931. Dr. Broughton, who is a Cambridge graduate, trained at the London Hospital and subsequently took the D.P.M. at Leeds in 1936 and the D.P.H. a year later. He served in the R.A.F.V.R. as a squadron-leader during the war and has been honorary physician to the Batley and District Hospital for some years. He was honorary secretary of the Dewsbury Division of the British Medical Association in 1936-7 and chairman of the Division in the following year.

Visitor to U.S.A.

Dr. William W. Mushin, of the Department of Anaesthetics, Welsh National School of Medicine, is going to San Francisco early in March as visiting professor of anesthesiology at Stanford University. He will give a course of lectures and attend a conference arranged by the California Society of Anesthesiologists.

COMING EVENTS

Kelynack Memorial Lecture

The second Kelynack Memorial Lecture will be delivered, under the auspices of the Society for the Study of Addiction, by Dr. P. O. Wolff, of Buenos Aires, at the Royal Society of Medicine, 1, Wimpole Street, London, W., on Thursday, March 3, at 5 p.m. His subject is "Problems of Drug Addiction in South America." Admission to the lecture is free.

Officers' Reunion Dinner

The annual dinner for officers and ex-officers of the R.A.M.C. who served in any formation in the Second Army from 1944-5 will be held at Simpson's Restaurant, Strand, London, W.C., on March 3, at 7 for 7.30 p.m. Brig. H. L. Glyn Hughes, C.B.E., D.S.O., M.C., will be in the chair. Dinner jacket or lounge suit may be worn, and tickets, price 21s. (exclusive of wines), can be obtained on early application to Dr. R. Gwyn Evans, 33, Sandford Road, Mapperley, Nottingham, or Dr. R. E. G. Ormrod, 4, Aubrey Road, London, W.

Guy's Hospital Dental School

The annual clinical meeting of Guy's Hospital Dental School will be held in the dental department of the hospital (London Bridge, London, S.E.) on Saturday, March 5, when there will be morning and afternoon sessions. Members of the staff will demonstrate modern dental procedures, and cases of clinical interest will be shown.

Address by Dr. Charles Hill

Dr. Charles Hill will address a meeting arranged jointly by the Crewe and North Staffs Divisions of the B.M.A. at the Town Hall, Crewe, on Sunday, March 6, at 3 p.m. All members in Cheshire, Staffordshire, and Shropshire are invited.

South Wales Medical Ex-Service Association

The South Wales Medical Ex-Service Association will hold its third annual reunion in March. All medical men who have served in either world war are eligible to attend. Owing to the relaxation of certain food restrictions it has been possible to arrange a dinner, and this will be held at Park Hotel, Cardiff, on Saturday, March 5, at 7 for 7.45 p.m., with Colonel J. P. J. Jenkins in the chair. Tickets (12s. 6d. each) may be obtained from the honorary secretary, Mr. Cecil W. D. Lewis, Surgical Unit, Cardiff Royal Infirmary. The unveiling and dedication of the memorial to former students of the Welsh National School of Medicine who lost their lives in the war will take place in a service to be held in the Chapel of Cardiff Royal Infirmary on Sunday, March 6, at 10.30 a.m. The memorial, in the form of a stained-glass window and plaque, will be unveiled by Sir Frederick Rees and dedicated by the Lord Bishop of Llandaff.

Gynaecology Conference

A conference on malignant disease of the female pelvic organs will be held at Newcastle-upon-Tyne on April 1-2 under the auspices of the Departments of Gynaecology and Radiotherapy of the Royal Victoria Infirmary and the Medical School, King's College. The Introductory Address will be given by Mr. Victor Bonney at 5.30 p.m. on April 1, and there will then be a discussion on the treatment of carcinoma of the cervix, at which the principal speakers will be Dr. Malcolm Donaldson, Mr. George Blomfield, and Mr. David Currie. On April 2 papers will be read by Mr. Allan Brews, Dr. A. Glucksmann, Mr. Harvey Evers, and Dr. C. W. Taylor, and there will be a demonstration in the Newcastle Regional Cancer Organization's gynaecological unit at the Queen Elizabeth Hospital, Gateshead. All communications concerning the conference and the names of those wishing to attend should be forwarded as soon as possible to Mr. Stanley Way, Royal Victoria Infirmary, Newcastle-upon-Tyne.

SOCIETIES AND LECTURES

Monday

HUNTERIAN SOCIETY.—At the Mansion House, London, E.C., Feb. 28, 5.30 p.m. "Personal Experiences." Hunterian Oration by Sir H. H. Oliver.
LONDON UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, London, W.C., Feb. 28, 4.45 p.m. "Haem Pigments in Man," by Professor C. R. Martin.
MEDICAL SOCIETY OF LONDON.—11, Chandos Street, Cavendish Square, W., Feb. 28, 9 p.m. "Richard Brinsley Sheridan—Before and After." First lecture in the series by Dr. Horace Evans.

Tuesday

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., March 1, 11 a.m. "Keratinoderm a Benign Disease," by Dr. A. H. Hirst.
LONDON UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, London, W.C., March 1, 5.15 p.m. "Baroreceptor Activity in the Dog," by Dr. A. Scherzer.

Wednesday

EDINBURGH CLINICAL CLUB.—At Princess Margaret Rose Hospital for Crippled Children, March 2, 4 p.m. Visit conducted by Mr. W. V. Anderson.
INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., March 2, 11 a.m. "Skin Diseases of Possible Venereal Origin" and "Differential Diagnosis of Genital Dermatoses," by Dr. W. N. Mascall.
LONDON COUNTY MEDICAL SOCIETY.—At Dulwich Hospital, East Dulwich Grove, London, S.E., March 2, 3 p.m. Clinical meeting.

Thursday

FACULTY OF HOMOEOPATHY.—At Royal London Homoeopathic Hospital, Great Ormond Street, London, W.C., March 3, 3 p.m. "Homoeopathy's Way to Recognition," by Dr. E. K. Ledermann.
INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., March 3, 11 a.m. "Collection of Specimens for Laboratory Investigation," by Dr. R. Thomson.
LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At B.M.A. House, Tavistock Square, W.C., March 3, 8.30 p.m. "The Care of the Aged." Discussion.
LONDON UNIVERSITY.—At Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E., March 3, 4.30 p.m. "Physiology of the Vestibular Apparatus," by Mr. Terence Cawthorne.
LONDON UNIVERSITY.—At Large Lecture Theatre, St. George's Hospital Medical School, Hyde Park Corner, London, S.W., March 3, 4.30 p.m. Lecture-demonstration: "Psychiatry."
LONDON: UNIVERSITY COLLEGE.—At St. Thomas's Hospital Medical School, London, S.E., March 3, 5 p.m. "Ionic Exchange and Electrical Activity in Nerve and Muscle," Special University Lecture by Dr. A. L. Hodgkin.
ROYAL PHOTOGRAPHIC SOCIETY: MEDICAL GROUP, 16, Prince's Gate, London, S.W., March 3, 7.30 p.m. "Somatotyping—Purpose and Method," by Dr. J. Tanner.

Friday

LONDON CHEST HOSPITAL, Victoria Park, E.—March 4, 5 p.m. "Atypical Pneumonia," by Dr. Bertram Jones.
ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle Street, London, W., March 4, 9 p.m. "The Foundation of the Royal Institution" by Professor E. K. Rideal, D.Sc., F.R.S. (The Institution was founded on March 7, 1799).
ROYAL MEDICAL SOCIETY, 7, Melbourn Place, Edinburgh, March 4, 8 p.m. Address by Mr. G. K. M. Hall.

Saturday

KENT PAEDIATRIC SOCIETY.—At Farnborough Hospital, March 5, 2.30 p.m. "Congenital Heart Disease," by Dr. Charles Baker.
NUTRITION SOCIETY.—At London School of Hygiene and Tropical Medicine, Keppel Street, W.C., March 5, 10.30 a.m. "Nutrition and Fertility." Speakers, Dr. H. E. Magee, Dr. John Hammond, Dr. A. Walton, Dr. Joseph Edwards, Dr. S. A. Folley, and Professor A. St. G. McC. Huggett.

APPOINTMENTS

Dr. Margaret Sutill, M.B., B.S., who has been on the staff of the British Council since May, 1945, has been appointed Director of the Medical Department in succession to Dr. G. A. W. Angus.

MIDDLEMISS, JOHN H., M.D., D.M.R.D., F.F.R., Director, Radiodiagnostic Department, United Bristol Hospitals.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Feast.—On Feb. 14, 1949, at Birmingham, to Beryl, wife of Dr. R. G. Feast a daughter.
Semple.—On Feb. 6, 1949, at Middlesex Hospital, London, W., to Dr. Alison Semple (née Cruickshank) and Dr. Robert Semple, a daughter.

MARRIAGE

Bury.—Clark.—On Feb. 19, 1949, at Caxton Hall, Westminster, London, S.W. John Duncan Bury, M.R.C.S., L.R.C.P., son of Major F. W. Bury, M.Sc. F.R.I.C., and Mrs. F. W. Bury, of Northam, Devon, to Doris Sylvia Clark daughter of Mr. and Mrs. John Clark, of Kenton, Middlesex.

DEATHS

Marks.—On Feb. 4, 1949, Urban Marks, M.R.C.S., L.R.C.P., of Bishopston Swansea, aged 58.
Marsh.—On Feb. 6, 1949, at Greenways, Llanfrehfa, Newport, Mon., Octavius de Burgh Marsh, O.B.E., M.B., B.Ch.
Moseley.—Recently, John Gimson Moseley, M.D., of Jamaica Park.—On Feb. 2, 1949, Griffith Wynn Vaughan Parry, M.R.C.S., L.R.C.P., of Camden House Betchingley, Surrey.
Reagan.—On Jan. 31, 1949, at Bootle, Peter Leo Reagan, M.B., B.Ch., aged 60.
Richards.—Recently, Gwilym Caradog Richards, M.B., Ch.B., Captain, R.A.M.C., aged 25.
Spriggs.—On Feb. 4, 1949, Sir Edmund Ivens Spriggs, K.C.V.O., M.D., F.R.C.P., of Coed Marchan, Ruthin, Denbighshire.
Thoms.—Recently, Geoffrey Sumdrell Thoms, M.B., Ch.B., Surgeon-Commander R.N.—On Feb. 12, 1949, at Cleff, David Tindal, M.D., F.R.F.P.S. Glas., aged 93.
Witham.—On Feb. 3, 1949, at Church Street Nursing Home, Bath, Frank Witham, M.R.C.S., L.R.C.P., Major, R.A.M.C. retired, aged 83.
Zane.—On Feb. 7, 1949, at Florence Nightingale Hospital, London, N.W., Mary Victoria Zane, M.B., Ch.M.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Excretion of Barbiturates

Q.—What is the rate of excretion of the barbiturates? A recent article states that phenobarbitone is excreted at the rate of only 3% in 24 hours. Is this be so, continuous small doses would surely produce a dangerous accumulation in a short time yet I have known cases in which this drug has been taken regularly for years with no apparent ill effects.

A.—No single figure for the rate of excretion of the barbiturates can be given. Some barbiturates such as hexobarbitone or thiopentone are broken down, chiefly in the liver and are not excreted as barbiturates at all. Barbitone and phenobarbitone after ordinary therapeutic doses, consistently appear in the urine unchanged but even so a part of the dose is destroyed in the body. The part played by the liver in destroying phenobarbitone has been demonstrated in rabbits and cats in the following way. Chloroform anaesthesia, which depresses liver function, is maintained for two hours. Then 24 hours later phenobarbitone is given. It causes deep depression for long periods, and the animals may die from doses which are only half the average fatal dose. Thus damage to the liver by chloroform prevents adequate detoxification of phenobarbitone. Hence, while 3% of phenobarbitone is excreted in 24 hours, a good deal more is destroyed in the liver. The mere fact that some is excreted however means that destruction in the liver is far less efficient than it is when thiopentone is given. Since there may be a great difference between individual patients in their ability to detoxify phenobarbitone, it follows that in some people overdosage may easily occur.

Calculi in a Paraplegic

Q.—A man aged 21 has a complete paraplegia as a result of (?) myelitis in childhood. Although he is lifted occasionally into an invalid chair he mainly lies flat in bed. As a result he has recently begun to pass softish renal stones which usually become impacted just inside the external urethral orifice, so far it has been possible to remove them with forceps. Is there any drug or treatment which will prevent the formation of the stones and dissolve those probably already present in either the bladder or kidneys or both? He is incontinent but gets an erection occasionally.

A.—Not enough information is given to decide what would be the ideal treatment in this case. It is important to know whether there is evidence of infection of the urinary tract, which is likely in an incontinent patient. Radiology would almost certainly reveal the site of calculi which are already present. The stones are very likely to be composed of calcium phosphate, but it would be useful to confirm this by chemical means. It is clear, therefore, that treatment could be best given in an institution equipped to carry out the investigations. The following regimen should, however assist in preventing the formation of further stones. (a) Four litres of fluid should be taken daily to ensure a dilute urine. (b) An acid ash diet should be given with a minimum of milk—a high calcium diet has been shown to increase the urinary calcium excretion. (c) The reaction of the urine should be tested should it remain neutral or alkaline, regular ammonium chloride should be prescribed to ensure acidification. (d) The position of the patient should be changed as frequently as possible. It would be useful if he could be lifted into the invalid chair at least once daily. (e) Supplementary vitamins especially vitamin A should be given. (f) Any coexistent urinary infection should be appropriately treated according to the organism present.

To dissolve stones which are already present the use of the so called 'solution G' of citric acid has been advocated.

R	G
Citric acid (monohydrate)	32.3
Magnesium oxide (anhydrous)	3.8
Sodium carbonate (anhydrous)	4.4
Distilled water	to 1 litre

As this must be irrigated through a urethral or ureteric catheter its use would be practicable only if he could be admitted to a well-equipped hospital. Surgery should of course be contemplated if any large calculi are shown to be present by radiology.

Keloid

Q.—(a) What is the most recent treatment for keloid and hypertrophic scar following an injury to the elbow and knee in a girl aged 12? The keloid is in the form of a raised scar about the size of a small marble and there is no tentacle formation.

(b) A young patient had a boil on her cheek some four months ago. The scar is now healing well and colour is becoming normal but there is a considerable degree of puckering. What is the most efficient treatment to improve this?

A.—(a) Treatment for keloid formation is as unsettled as it ever was, but most authorities are agreed that preliminary treatment with x rays followed by excision and further post operative x irradiation offer the best chance of success. It should be pointed out, however that many disappointing results follow the use of x rays, years later x ray dermatitis may result. The irradiation should be done only by a competent radio therapist skilled in this particular work. Excision by itself, while it may be satisfactory, can also be disappointing the outcome depending on the site of the keloid and its relation to lines of skin tension. A plastic surgeon should be consulted on the advisability of operation. The hypertrophic scar in a girl aged 12 mentioned in the question is a case in point. Keloids are apt to recur in young people and this is particularly so on extensor surfaces such as those of the elbow and knee. Excision in an adjusted line would probably be advisable. X rays would not be likely to help.

(b) The scar should be left for at least six months to resolve. If puckering still persists, careful excision by a competent plastic surgeon would be advisable.

Innervation of Uterus

Q.—(a) From what cord level does the sympathetic supply to the uterus come? Does it contain sensory as well as motor fibres and do these emanate from the same cord level? (b) Is there a parasympathetic supply to the uterus? If so what are its function and its cord level? (c) What is the effect of spinal analgesia and of caudal analgesia?

A.—(a) Knowledge about the innervation of the uterus remains incomplete and uncertain, and the extensive literature dealing with clinical and experimental observations in the human being and animals is confused and sometimes contradictory. Without listing all the issues concerned it can be stated that the elucidation of this problem is far more difficult than appears at first sight and most of the following statements should be regarded as general opinions requiring much qualification rather than as facts.

Although it is usual when innervation is considered to think in terms of the muscle elements of the uterus the vascular elements also have an autonomic nerve supply, and this may be important. For instance, the state of the circulation may have some bearing on sensations of pain arising within the uterus. The nerves in question probably accompany and are intimately associated with the main blood vessels to the uterus. As regards the nervous control of this organ whatever be its ordinary purpose it is not essential to the process of parturition and the uterus can empty itself with reasonable efficiency when all nervous connexions are severed. The main sympathetic supply passes to the uterus by way of the superior hypogastric plexus (presacral nerves) and the inferior hypogastric plexus. Stimulation of these nerves is thought to bring about contraction of the circular muscle fibres particularly those in the lower part of the uterus and upper part of the cervix. Sympathetic impulses therefore tend to hinder distention of the

cervix, and the general effect on the expulsive action of the uterus is inhibitory. There is some dispute about whether the presacral nerves carry sensory impulses too, but most authorities believe they do, and this is in part at least the basis of the operation of presacral neurectomy for spasmodic dysmenorrhoea. In a letter to this *Journal* (April 10, 1948, p. 706) Dr. J. Donaldson Craig pointed out, on embryological grounds, that the sympathetic nerves to the uterus are derived from segments D11 to L2, but some authorities have put the level at D5 to D8. It is also possible that some of the sympathetic nerves to and from the uterine muscle accompany the ovarian vessels.

(b) The parasympathetic nerves come from S2, S3, and S4 segments, and they reach the uterus by way of the inferior hypogastric plexus. The traditional view is that when stimulated they cause contraction of the detrusor muscles of the upper segment. However, some believe there is no parasympathetic motor supply to the uterus. Sensory impulses, especially those arising in the cervix, also travel through these nerves.

(c) The effect of spinal analgesia varies with the level of the nerve block. It probably has to reach L1 or even D11 or D10 before the sensation of a labour "pain" is abolished. With the level of analgesia sufficiently high to permit caesarean section the uterine muscle contracts strongly, sometimes almost in a tetanic fashion, and the uterine wall becomes blanched. Dilatation of the cervix is said to be hindered. This may represent the unopposed action of motor sympathetic impulses. If so, it suggests that sensory nerves are connected with the spinal cord at a lower level than the motor ones. With very low spinal analgesia this strong uterine contraction may not occur.

Caudal analgesia differs from spinal analgesia only in that the analgesic solution is applied to the nerve fibres extrathecally instead of intrathecally. The effects are similar, except that the contraction of the uterus is perhaps less violent and dilatation of the cervix is not significantly impeded. It is not clear why this should be so. Perhaps the height and completeness of the block are less constant, and in any case some observers hold that spinal analgesia does not interfere with cervical dilatation. With either spinal or caudal analgesia the pelvic floor reflex is lost and the patient finds it difficult, if not impossible, to "bear down" in the second stage and to effect delivery.

Varicocele

Q.—Is there a satisfactory cure or treatment for a male patient of 30 suffering from varicocele, which is causing considerable discomfort? Is operation recommended? If so, what operation, and what are the late results?

A.—In the ordinary course of events operation for varicocele should be avoided for as long as possible, the condition often being symptomless and the patients introspective in type. If it is causing definite discomfort, presumably from a dragging pain, surgery is advisable. Varicocele can be cured by injection, but the technique is a difficult one and reactions are apt to be severe.

The operation is performed through a small inguinal incision, the cord being exposed as it emerges from the external abdominal ring. The varicose veins of the pampiniform plexus are dissected out. It is wise to leave one or two radicles, as the chances of producing a secondary hydrocele are thereby considerably lessened. Apart from these radicles a length of the pampiniform plexus is excised, and by drawing the cut ends together the testicle is raised to the required extent. The actual length of veins excised will vary from patient to patient and approximately between two and four inches. A scrotal support for the immediate post-operative month is advisable. Late results in well-selected cases are entirely satisfactory.

Risk of Inherited Defects

Q.—Of three offspring born to normal healthy parents, with no relevant family history, the second had a spina bifida and the third was a mongol. Is there any recognized association between these conditions? Is there any reason for expecting defects in the offspring of the remaining healthy child?

A.—It is very unlikely that the occurrence of spina bifida and mongolism in this sibship is anything more than a coincidence. Both conditions have some hereditary basis, but other factors, presumably environmental, are relatively much more

important, so that familial incidences are very low. Hence the chance that the healthy child will have defective offspring is little if at all greater than would be the case with any random person with no such family history. If the mother is still of child-bearing age, the chance that another child will be deformed is undoubtedly somewhat greater than in a random pregnancy; even if she is elderly, however, it should be no worse than, say, 1 in 10.

Deafness and Tinnitus

Q.—A patient has had gradually increasing conductive (middle-ear) deafness, due to otosclerosis, for 17 years, and a hearing-aid has been used for the last six years. Would a fenestration operation help her, as there are no obvious changes in the internal ear? What is the prognosis after the operation? She also suffers from severe noises in the head: would the operation relieve this condition?

A.—If bone conduction for the frequencies 512, 1,024, and 2,048 double vibrations is good, fenestration should help. But the patient should be told that not even the (theoretically) most suitable case can be guaranteed any improvement. In many cases the restored hearing is lost from closure of the new fenestra or from serous labyrinthitis. Tinnitus is relieved in only a minority of these cases, and bromides or barbiturates may be required.

NOTES AND COMMENTS

Ammoniacal Dermatitis in Infants.—Dr. N. R. CARLSON (Pevensey Bay, Sussex) writes: In "Any Questions?" (Jan. 22, p. 164) there is an excellent account of ammoniacal dermatitis in infants. I would like to remark on the success I have had in using acid sodium phosphate (5 gr.) instead of alkalis such as citrate. The ammoniacal smell rapidly disappears, but soon returns if the acid phos. is withdrawn without first correcting the diet. It is a little difficult to explain why the acid phos. works so well. It may be that there is excessive loss of acid in the faeces (as these are always frequent and acid in reaction in this condition), thereby leading to a tendency to alkalaemia and an alkaline urine which cannot neutralize the ammonia being formed by the urea-splitting organisms or ferment. The acid phos. would give a slightly acid urine which could neutralize or buffer the ammonia. As regards the local treatment, I have found that a "sheet" of tulle gras laid over the excoriated area and dusted with boric powder protects the raw area and allows it to heal rapidly.

Fat Intolerance.—Dr. M. D. WRIGHT (London, W.6) writes. Answering a question on fat intolerance in "Any Questions?" (Jan. 22, p. 164) you recommend for vitamin A two tablets daily of carotene, each containing 4,500 units—a total of 9,000 units of carotene, of which rather over half is equivalent in units to vitamin A. In 1945 the vitamin A Subcommittee of the Medical Research Council published in *Nature* (156, 11) records of experiments on man in which it was shown that defective night vision and low plasma-vitamin A values—arising through experimental deprivation of carotene and of all sources of preformed vitamin A—improved in one case promptly on a daily dose of 2,600 i.u. of carotene. In another case the improvement required about five months of the same dose. Too little precise experimental work is recorded on man, but the authors consider that even in the presence of deficiency symptom 2,600 i.u. carotene is sufficient to cure and 5,000 i.u. enough provide a reasonable margin of safety. The world shortage of vitamin A sources is still such as to make over-usage undesirable and the work quoted above gives useful guidance based on critical observations.

Correction.—Mr. E. R. BRANSBY, Ph.D., writes: In our paper on the diet, haemoglobin values, and blood pressures of Olympic athletes (Feb. 19, p. 300) an error inadvertently crept in. It is stated (p. 30) that the average calorie intake of 3,350 daily is about the average need of a man engaged on light work. This should, of course, be moderately heavy work.

All communications with regard to editorial business should be addressed to the EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Attilio Westcott, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* and its Supplements. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY FEBRUARY 26 1949

THE SECRETARY REPORTS

CONSTITUTION OF THE ASSOCIATION

Although it cannot be pretended that it is an easy document, it is hoped that the Council's Report on the Association's constitutional problems will be widely read. It does not deal with the problem whether the trade union conception generally is one which the profession generally would accept. It is a technical document which, beginning with two recognizable defects in the Association's present constitution, seeks to answer the question whether trade union status in one form or other would solve our problems. It emerges that if our legal advisers are right the medical profession could never create a trade union which would enjoy the protection that the law affords to trade unions generally. That protection, it seems, is limited to associations of masters or workmen, and legally we are advised that doctors are neither.

The Report goes on to consider other ways of remedying the defects. Ultimately it comes down on the side of a parallel body which may be regarded as the Independence Fund Trustees in permanent form. The question may well be asked, as it was at the Council, whether such a body should have members. As one member of the Council put it, one cannot belong to a document. What influenced the Council in deciding against a body with membership was the need to maintain the position of the Representative Body as the policy-making body and the Council as its executive, utilizing the new body to do those two things which, by its constitution, the Association is unable to do. If such a body were to have membership it might well be considerably less than that of the Association. It would follow that the members would appoint and instruct the trustees with the danger that the policy of the trustees might differ from that of the Representative Body. In short, it is intended that the Association should remain the representative body of the profession, the Board of Trustees, which would consist of members of the Council, acting in those fields in which the Association cannot, because of its constitution, safely operate.

Clearly something more than a Central Board of Trustees will be needed if the new body is to be effective for the purposes for which it is proposed it should be created. After all, those purposes include the collection of money and the establishment of a machinery which can swiftly come into operation in the event of dispute. It will be for the Board of Trustees, should the Representative Body approve the Council's proposals, to set to work to establish a machinery including local machinery. It is probable that, just as the Independence Trustees advised the establishment of local Independence Committees, the Board of Trustees will advise the formation of local units of the Guild, continuous with the Divisions of the Association. In its report the Council has concentrated on general principles, leaving the Board, if and when established, to get down to the brass tacks of detailed central and local organization.

Betterment

The recommendations of Lord Chorley's Committee on the Remuneration of Higher Civil Servants are of great interest, particularly when the recommended rates of remuneration are compared with those obtaining in 1939. Some of the more important details are set out in simplified form in the accompanying table.

In pre-war days, when the scale for the post of Permanent Secretary of the Ministry of Health was £3,000, the salary for

the post of Chief Medical Officer of the Ministry of Health, according to Whitaker, was £2,200. To-day, when the salary for the Permanent Secretary post stands at £3,500, that of the post of Chief Medical Officer—a salary personal to the present holder—is £3,000. The Chorley Committee does not put forward recommendations for medical officers as such, but states

Administrative Class Salaries

Grade	1939	Jan. 1 1946	Chorley Committee Recommendation
	£	£	£
Permanent Secretary to the Treasury	3,500	3,750	5,000
Other Permanent Secretaries	3,000	3,500	4,500
Deputy Secretary	2,200	2,500	3,250
Under Secretary (a grade which existed in some depts. only)	1,900	2,000	2,500
*Principal Assistant Secretary	1,700	—	—
Assistant Secretary	1,150-1,500	1,320-1,700	2,000

* The grade of Principal Assistant Secretary was abolished (although a few members of the obsolescent grade still remain) and the new grade of Under Secretary introduced into all Departments.

under the heading of "Other Classes" that they should maintain their present relationships with the Administrative Class. This should bring the remuneration of the Chief Medical Officer to approximately £4,000 a year. Similarly, the remuneration of other medical officers of the Ministry in comparable senior grades will, it is assumed, be raised in relation to increases in the remuneration of the Administrative Class.

In addition to these salaries, there are at present non-contributory pension arrangements. The Government has accepted the recommendations of the Chorley Report in principle, but has decided on a gradual application.

Visitors from Overseas

News has reached me, indirectly and not officially, that the Ministry has changed its view on the subject of the treatment of visitors from overseas. It has now made a rule, I understand, that the benefits of the National Health Service do not extend to overseas visitors, whether foreign nationals or citizens of the Commonwealth or Colonies, if those visitors come to this country for the specific purpose of using the Service. If, on the other hand, they should fall ill whilst here on a visit, they are entitled to use the National Health Service. Others will, no doubt, offer views about the steps to be taken by the practitioner to find out what prompted a visitor to come to this country. Advice will, no doubt, be offered on what measures the doctor should take if a visitor alleges that he came to this country to see his Aunt Mabel, though in fact he called on the doctor before calling on Auntie, if indeed Auntie exists!

But an issue of first importance is the legal one. Either the Act does or it does not entitle foreign visitors to use the National Health Service. If it does so entitle them, then a Government Department has no business to make rules which deny the Service to persons to whom the Act gives an entitlement. If, on the other hand, it does *not* entitle foreign visitors to use the Service, then the law is being broken by affording its facilities to any visitor from overseas. The Act does not differentiate between visitors to this country on any basis of the motives which inspired them to come. Concealed behind this latest decision is the important issue of the power of a Department to make or break the law.

National Health Service

SUPPLEMENTARY OPHTHALMIC SERVICE FEE REDUCED

Shortly after the introduction of the National Health Service the Ministry of Health became perturbed at the rate of remuneration of practitioners participating in the Supplementary Ophthalmic Service. It therefore collected details from a number of executive councils of the cases in which the highest sums had been paid. The area covered in this survey was about half the country, and the practitioners in respect of whom information was obtained represented roughly 5% of the practitioners operating the Supplementary Ophthalmic Service in those areas. There was no definite information about the average time taken by practitioners concerned for each sight test, since it was not known what portion of their time was devoted to the work. Nevertheless, bearing in mind that the practitioners had other commitments such as general practice or a hospital appointment, the figures supported an assumption that in those specific cases the time given to each patient was appreciably less than half an hour—the estimate on which the fee of £1 11s. 6d. had been assessed.

The survey could not, however, be regarded as a comprehensive or impartial inquiry, nor could it fairly be taken as an indication of the time devoted to each patient examined by the average ophthalmic practitioner. Indeed, the Ministry itself recognized that a further and more comprehensive inquiry was desirable, and at a meeting with the Ophthalmic Negotiating Committee in December, 1948, it suggested that such an inquiry should be carried out. Nevertheless it took the view that the information it had already obtained was *prima facie* evidence that the original estimate of half an hour was no longer correct, and proposed that there should be an immediate provisional reduction in the fee.

The Ophthalmic Negotiating Committee persuaded the Ministry that the inquiry should come first, and assured the Ministry that if such an inquiry was made it would be prepared to reconsider the question of the fee in the light of its findings. It was agreed that Professor Bradford Hill should be asked to advise on the conduct of the inquiry, but Professor Bradford Hill considered that an inquiry whose object would be known in advance to those participating could have no precise statistical value.

The Ophthalmic Negotiating Committee again discussed the position with the Ministry on Feb. 7, when the Department expressed the view that in the absence of an immediate inquiry it felt justified, as a result of the preliminary inquiries it had made, in imposing a provisional reduction in the fee. It agreed that a full and impartial inquiry was still desirable, and that an endeavour to carry it out should be made as soon as practicable. It also gave an assurance that if the inquiry revealed that the reduction was not fully justified this factor would be borne in mind in adjusting the fee.

The Ministry suggested that the fee should be adjusted on the basis of three cases per hour, and asked whether the Committee was prepared to agree or to make a revised estimate on the experience of the first six months' working of the Service. The Committee urged that an estimate of 20 minutes a case was too low in view of the type of case normally referred to ophthalmic practitioners and to the clerical work involved. This view has been accepted by the Ministry in reaching a decision. At the same time the Committee expressed the view that an estimate at this stage could have no significant value in comparison with a factual inquiry which would reveal the actual position. It could still see no justification for a reduction in the fee before a full and impartial inquiry had been made to verify whether or not the original estimate was correct. The Committee therefore again urged that the inquiry should precede any modification in the fee, and stated that if the Ministry did not adopt this course, but imposed a reduction of fee, it must be on the Department's responsibility.

The following letter has now been received from the Ministry:

I am directed by the Minister of Health to say that he has had under consideration the remuneration paid under the National Health

Service in the light of experience gained in the operation of the Service. The fee paid for sight tests carried out by ophthalmic medical practitioners is based on the assumption that the average time taken to complete a sight test is half an hour. Preliminary inquiries show that in a number of cases a shorter time is being taken. After discussion with representatives of the profession the Minister has accordingly come to the conclusion that a provisional reduction ought to be made. He accordingly proposes to provide that as from April 1 next the fee should be reduced from the present £1 11s. 6d. to £1 5s. on the basis of an average timing of 24 minutes. The Minister would propose to discuss further with the profession what steps can be taken to investigate the average time taken for a sight test, and if the proposed investigation should reveal that the reduction is not fully justified an appropriate adjustment would be made in the fee subsequently fixed. A similar letter has been sent to the Faculty of Ophthalmologists.

TRAVELLING EXPENSES FOR INTERVIEWS

The Ministry of Health has informed executive councils that they should refund travelling expenses when they interview short-listed applicants for an advertised vacancy. The full cost of a third-class return railway fare or bus fare from the applicant's ordinary place of residence is allowed when the sum exceeds 5s. Subsistence allowances are not payable.

ATTENDANCE AT COMMITTEE MEETINGS

The Ministry of Health states that in some instances professional officers—e.g., medical superintendents and matrons—are being excluded from meetings of management or house committees at which matters in which they are concerned are under discussion. The Minister considers it essential that they should be present to advise committees on such matters unless special circumstances make it desirable that they should be temporarily absent.

For example, where a hospital in a group has a medical superintendent in charge, he should be given the opportunity to be present at committee meetings (including those of the management committee of the whole group) when the officers of that hospital are considered. Similarly, the matron of any hospital in a group should be present when nursing questions affecting her hospital are discussed.

EDUCATION AND MENTAL HOSPITALS

Hospital management committees of mental hospitals may arrange educational classes for voluntary patients now that the Education Act, 1944, has been amended by the First Schedule to the Education (Miscellaneous Provisions) Act, 1948. Committees may ask the Director of Education of the area in which the hospital is situated for assistance so far as local resources allow. Classes would normally be held at the hospital, but it might be of therapeutic value to allow voluntary patients to attend classes in local schools or other outside centres.

Non-voluntary patients are not covered by the Education Acts, but if classes would be of therapeutic value management committees may ask the local director of education for assistance in finding teachers. In this case the committees would have to meet the costs, because the Education Acts do not provide for a grant.

HOSPITAL PROVISIONAL CONTRACTS: CORRECTION

Under this heading we incorrectly stated in the *Supplement* of Feb. 19 (p. 82) that "consultants and specialists are negotiating their terms and conditions of service with the Ministry." In fact, proposals are under discussion between the Ministry and the Joint Committee of Consultants and Specialists. As stated in the *Supplement* of Jan. 29 (p. 49), the committee is not negotiating; at this stage it is advising the Ministry on the terms and conditions of service which might in the committee's view prove acceptable or more acceptable to consultants and specialists.

HEPASTAB FORTE

HEPASTAB FORTE is a highly concentrated extract of liver which has been prepared in our Nottingham laboratories as the result of research conducted by our own chemists in co-operation with clinicians in this country and abroad. It contains all the known anti-anæmic factors of liver, is highly refined, painless on

injection, and highly concentrated. Each 1 c.c. of Hepastab Forte is obtained from 100 G. of liver and is therapeutically equivalent to 4,000-5,000 G. of fresh liver by mouth.

Ampoules of 1 c.c.: single ampoules, boxes of 3, 6 and 12 ampoules. Rubber-capped vials of 10 c.c.

Literature and further information gladly sent on request to Medical Department.

BOOTS PURE DRUG COMPANY LIMITED, NOTTINGHAM, ENGLAND.

Compensation FOR THE SERIOUS LACK of FAT

World-wide rationing has reduced our fats and in consequence our fat-soluble vitamins. Angier's Halibut Liver Oil Capsules solve the problem of how the physician can prescribe the essential fat-soluble vitamins A & D, because Halibut Liver Oil is so rich in these natural vitamins that Angier's are able to put enough into two or three small, tasteless and easily swallowed capsules to provide the body's entire requirements for the whole day. Thus Angier's Halibut Liver Oil Capsules enable the physician to prescribe a preparation which can justly be expected to help in countering some of the more serious results of our dietary lack of fat.

FORMULA

Vitamin A: 32,000 International Units
Per gramme
Vitamin D: 2,500 International Units
Per gramme
Which represents per capsule:
Vitamin A: 4,500 International Units
Vitamin D: 420 International Units

ANGIER CHEMICAL CO., LTD., 24, CLEVERWELL ROAD, LONDON, E.C.I.

THE DIVERSITY OF INJECTABLE 'D'

Whether you are treating chilblains, urticaria, or other relatively common allergies, the use of Colloidal Calcium with 'Ostein' is equally wisely considered. To these conditions add neurasthenia, debility, capillary haemorrhage and delayed union of fractures... and you have some measure of the really wide sphere of usefulness of this preparation. Indeed, Colloidal Calcium with 'Ostein' can be relied upon whenever the need is for prompt stimulation of the reticulo-endothelial system.

GLAXO

COLLOIDAL CALCIUM WITH 'OSTEIN'

Contains 5,000 i.u. vitamin 'D' and 0.5 mg. of calcium per c.c. in colloidal solution.
Ampoules of 1 c.c. in boxes of 6, 12 and 100. Bottles of 30 c.c.

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX. BY2773434

MULTIVITE

Trade Mark

Multivite is the B.D.H. preparation of vitamins A, B₁, C and D, in chocolate-coated pellets which combine palatability with ease of administration.

Two pellets of Multivite provide the daily requirement of these four vitamins which are essential to health and, particularly in children, for normal growth. It is a valuable addition to the daily diet and invaluable when the diet is poor. A general feeling of well-being is noticeable after a course of Multivite, appetite is regained, listlessness disappears and susceptibility to infection is reduced.

Multivite is freely available in containers of 75 pellets.

CALL-UP OF DOCTORS TO H.M. FORCES

he Central Medical War Committee has been advised by the Ministry of Health that under the National Service Acts, 1948, which came into force on Jan. 1, 1949, the upper age-limit for the call-up of medical practitioners (specialists and general-duty medical officers) is 30 years. The only exception is the practitioner who makes a successful application to the Ministry of Labour, through the Central Medical War Committee, for postponement of call-up on grounds of exceptional personal hardship. In such cases the practitioner still retains his liability for recruitment beyond his 30th birthday for the length of the period during which the postponement certificate is in force.

In 1948 medical practitioners over 26 years of age were exempted from call-up as general-duty medical officers unless they had been granted deferment by the Central Medical War Committee to enable them to acquire further qualifications or special experience, in which case they were subject to recruitment until they reached their 30th birthday. The upper age-limit for the call-up of specialists during 1948 was fixed at 35 years. These arrangements are now superseded by the arrangements set out above.

Medical practitioners called up as from Jan. 1, 1949, will be required to serve for 18 months.

OPHTHALMIC GROUP

Members who are engaged wholly or predominantly in the practice of ophthalmology are invited to apply for membership of the Ophthalmic Group if they have not already done so. It is one of the Special Groups established by the Association, and seeks to provide a means whereby those members engaged in ophthalmology may bring their views before the Council for its consideration and support.

There are at the present time a number of problems of particular interest to ophthalmologists, and members of the Association who practise in this specialty may therefore wish to take a live interest in the activities of the Group and enjoy the opportunities which the Group provides of participating in the formulation of the Association's policy in matters relating to ophthalmology.

Forms of application for membership of the Group may be obtained from the Secretary.

British Medical Association

PROCEEDINGS OF COUNCIL

Wednesday, Feb. 16, 1949

THE CONSTITUTIONAL POSITION OF THE ASSOCIATION

Special Meeting of the Council of the Association was held on Wednesday, Feb. 16, for the purpose of considering the document entitled "Report of the Committee on the Constitutional Position of the Association" which is printed in this Supplement. Dr. H. Guy Dain, and in the concluding stages of the meeting Dr. E. A. Gregg, occupied the chair.

The Council first dealt with a report from the Group Committee concerned with full-time non-professional medical workers and laboratory and research workers. The Group Committee had suggested that the time was opportune for setting up a negotiating machinery to safeguard the interests of all full-time salaried practitioners who were not remunerated wholly through the National Health Service. They desired secure terms of remuneration not less favourable than those recommended for clinical specialists by the Spens Committee, which had not regarded it as within its terms of reference to make recommendations regarding the holders of such appointments, although it had expressed the view that to make such appointments sufficiently attractive an increased total remuneration should be offered.

The Council agreed to the request, and it was left to its chairman to consult with Mr. R. L. Newell, chairman of the Central Consultants and Specialists Committee, with regard to the setting up of a special committee, including members of the Council, to consider the subject and to make representations to the appropriate quarters.

Protection of the Interests of the Profession

The Chairman of Council, in introducing the report of the Committee on the Constitutional Position, reminded the Council that at the last Representative Meeting there was a demand in some quarters that the Association should be converted into a trade union. In the present Association charter there were two clauses, required by the Board of Trade, which limited the action that the Association could take in certain eventualities in support of its members. To convert the Association into a trade union would mean winding up the existing body and distributing its assets among its members, so that if a trade union were started it would start "naked"—an impossible

position. Moreover, doctors being neither "masters" nor "workmen," and not "employed in trade or industry," no benefit from trade union status would be derived under the Trade Disputes Act, 1906, Sect. 3 and 4, which afforded immunity from legal proceedings in respect of certain acts which ordinarily would be actionable wrongs, provided that these acts were committed in furtherance of a trade dispute or committed by or on behalf of a trade union.

Dr. Dain went on to describe the proposals for the formation of a parallel body as set out in the report. He submitted the report to the members of Council, acknowledging the work of Dr. A. Macrae, deputy secretary, assisted by the chief clerk, Mr. Twelftree, in drawing it up, and he moved as a recommendation to the Representative Body at the forthcoming special meeting:

That for the better protection of the interests of the medical profession in disputes with public authorities and other bodies, a new body be established in the form of an independent board of trustees with power to organize and finance collective action by the profession, and to provide financial compensation to practitioners suffering financial hardship through participation in such collective action;

That the new body be entitled the British Medical Guild;

That the new body be constituted in accordance with the trust deed as drafted by the Association's solicitors.

Questions

In reply to questions, Dr. Dain said that general practitioners who had contributed to the National Insurance Defence Fund during the last thirty years would probably desire to continue to do so, and the existing Trust would control that Fund. Dr. J. B. W. Rowe asked whether the use of the title "British Medical Guild" would make it necessary to apply for another charter and whether this might not be refused. Mr. Taylor (Solicitor, Messrs. Hempsons) said that a guild was not necessarily a chartered body; there would be no need to apply for a charter for any express form of constitution merely because it expressed itself as a guild.

Dr. R. G. Gordon asked what sum of money was envisaged, supposing the Guild was formed and was to be effective. It

would be necessary to impress a hostile Minister with the funds available if he was to take the Guild seriously. Dr. Dain replied that a large sum would obviously be necessary. The Guild would be in a position to invite contributions from the profession in the same way as was the Independence Fund.

Dr. H. H. D. Sutherland asked how this parallel body would work in line with the present B.M.A. membership. He added that he was all in favour of the Trust, he disliked the idea of partaking in trade union activities, but he was uncertain how the 60,000 membership of the B.M.A. would be brought into line. The Chairman of Council replied that that was one of the problems which the committee had had to face in considering the possibility of setting up a trade union organization. A union could confer benefits only on its own members, but a large number of doctors would not wish to join a trade union nor to have part of their subscriptions go to a trade union, and a body with limited membership would not be able to protect the whole profession. The idea was that the Guild should be run by a board of trustees which would be constituted for the purpose, having their own officers and organization, but there would not be any "membership" of the new body, and the funds raised and the action taken would be to protect members of the profession, whether members of the Association or not. There would be no act of "joining." In reply to a further question by Dr. Sutherland, Dr. Dain said that the effectiveness of the new body would depend upon its representation of the public opinion of the profession. Only by the consent of the great majority of the profession would it be able to pursue the action it wished to take. It could not act in any matter on which the profession was sharply divided.

Dr. J. A. Ireland said that if this was a short-term policy it would be ineffective because of lack of money. He thought that a fund of anything less than £4 million would be useless. The idea was an excellent one, but he failed to see its immediate practical value. Dr. J. C. Arthur said that the response to an appeal for subscriptions would be disappointing if practitioners were still paying subscriptions to the National Insurance Defence Fund. The Chairman said that members would not be expected to contribute to both.

Mr. A. Staveley Gough said that such a Guild was necessary, and he approved its purposes and the suggested machinery. It might be true that doctors were neither masters nor workmen, but 99% of them had a "master" in the Minister, and it was necessary to organize on parallel lines to trade unions.

After further questions by Dr. J. A. Gorsky and others, the Secretary (Dr. Charles Hill) said that in the committee it was felt to be desirable that there should be no sharp contrast between the membership of the Association and any membership of a parallel body which might be set up. The 60,000 members of the Association included overseas members, and only 75% of the members in this country joined the Guild it would give a membership of something over 30,000, which, with a membership of 60,000, might give a wrong impression. The British Medical Association would be the body to which loyalty was due, and the new body would be in effect the instrument of the Association to do the two things which the Association was unable to do. These were the considerations which led the committee to decide to have a body to perform functions which the Association itself could not perform.

Dr. S. Wand supported the proposal as a means of overcoming the limitations imposed by the two articles of association. Did it matter about "membership" so long as the money was available and the necessary action could be taken? Dr. J. B. Miller said that trade unionists paid from one-fiftieth to one-eightieth of their wages to their union; on this basis, with an average income of £1,500 or £2,000, doctors would be required to subscribe only £20 to £30 per annum.

Dr. N. E. Waterfield suggested that a letter should go out with the document explaining points which were not clear. The Secretary mentioned the difficulty of simplifying a document with so many legal implications.

The Council then considered the report in detail, and some slight verbal amendments were made. In reply to Dr. Liston, who said that there had been no definition of "master" and "workman" in regard to the medical profession, and asked what would be the effect of a court decision on this point, the

Chairman of Council said that the body it was proposed to set up could easily be converted into a trade union should occasion arise.

The Question of Membership

Dr. Sutherland moved an amendment to Para. 26 of the report, to insert the words "open to all medical practitioners domiciled in the United Kingdom," thus giving the new body a membership, and this was seconded by Dr. Gorsky.

Dr. J. G. Thwaites said that at first sight it appeared to be an advantage to have a membership, but really it would be a weakness, unless membership included all the medical practitioners in the country. The important thing was to have an organization which could translate into action the feeling of the profession. Dr. J. C. Arthur said that a number of members of the Association wanted a trade union, and if simply offered this Guild they would say that the Council was doing what it did before—giving them little more than a body of trustees. It was not necessary that every doctor should be in the organization, but there should be a sufficient number of doctors willing to act in accordance with the terms of the Guild. He thought there should be a list of terms and conditions to which members of the Guild would be required to subscribe, and then when it was known how many members would join a decision could be made whether the Guild should be formed.

Lord Horder said that it was a little difficult to get the concept of a body which had no members. General opinion within the profession would ultimately decide issues, but how was this to be canalized? Would the Guild express itself through the Representative Body?

The Secretary said that the Representative Body would continue to express the views of the Association, and the Council would remain its instrument. It was contemplated that the Council would automatically be the governing body of the new Guild, in the same way as the old Insurance Acts Committee were the trustees of the National Insurance Defence Fund. If a separate membership were established it could not be ensured that the governing body would consist of the same persons or have the same policy.

Dr. S. Wand could not see the advantages of having a membership. If there was a membership the choice might be between membership of the Guild and of the Association leading to a split profession. Mr. Dickson Wright thought that to insist upon a membership would be to weaken the position. What they wanted was a parallel body to do the work when the time came. Dr. Gray also said that this was a fighting machine, part of the Association organization, but with certain names and so forth attached to it because of legal difficulties.

The amendment was lost.

The Secretary, replying to further questions, said that the policy of the Association would still be determined by the Representative Body, and the Council would continue to act as its executive, but would also come into action as trustees for the Guild when such action was desirable inasmuch as the Association by reason of its constitution was unable to take the necessary action.

Dr. O. C. Carter asked about the relationship between the Guild and the new body. The Secretary said that the same considerations as applied to the Association applied to the Guild, but the field of what the Guild might or might not do had not been explored, and it might be left to the Journal Committee to consider the matter. Mr. Lawrence Abel said that it was important that the Council could instruct the Journal to publish anything given to it for publication by the Board of Trustees.

It was agreed that the Constitution Committee should consider further this matter of publication and also of local organization of the Guild. In reply to a further question the Secretary said that once the Guild was formed the Trustees would issue an appeal for subscriptions and donations, just as in the Independence Fund appeal. Details would be left to the Trustees. The Association as such could not subscribe; it could collect if it charged the cost of collection. Subscription by the National Insurance Defence Trust would be possible.

The recommendation was then agreed to for submission to the Special Representative Meeting.

REPORT BY THE COUNCIL ON THE CONSTITUTIONAL POSITION OF THE ASSOCIATION

I PRELIMINARY

1 The A.R.M., 1948 (Minute 65), referred to the Council, "for consideration and report to the Representative Body as early as possible," a number of motions relating to the establishment, in the form of a trade union or otherwise, of an organization for the better protection of the interests of the medical profession, particularly in connexion with terms and conditions of service under the National Health Service Act. The Council appointed a special committee "to inquire into the general question of the constitution of the Association. It has had before it, in addition to the motions mentioned above, similar resolutions adopted more recently by the Birkenhead and Wirral Division and the Newcastle-upon-Tyne Division.

2 The Council has examined the opinions obtained from learned Counsel on a number of occasions as to the powers of the Association and the limitations imposed by its present constitution, and throughout its deliberations it has had the advantage of continuous consultation with the Association's Solicitors. Briefly stated, the questions which the Council discusses in the paragraphs which follow are these:

(1) What are the disabilities from which the Association suffers by reason of its present constitution?

(2) Could the present constitution of the Association be so changed as to remove these disabilities; and precisely what advantages and disadvantages would result from such change?

(3) What other steps could be taken for the more effective protection of the interests of the profession?

II. LIMITATIONS OF THE ASSOCIATION'S CONSTITUTION

3 The Association is a limited liability company registered by the Board of Trade as a "company not for profit," and holding a licence from the Board of Trade to dispense with the word "limited" in its title. As an essential condition of the granting of this licence the Association was obliged to include in its Memorandum of Association the clause which appears as Clause 4 and the proviso which is attached to Clause 3, and it is because of these two sections of the Memorandum, both compulsorily imposed by the Board of Trade, that the Association is restricted in its efforts to protect the interests of the profession in medico-political conflicts.

4 Clause 3 of the Memorandum of Association is as follows:

"The objects for which the Association is established are

(1) To promote the medical and allied sciences and to maintain the honour and interests of the medical profession

(2) To hold or arrange for the holding of periodical meetings of the Members of the Association and of the medical profession generally.

(3) To circulate such information as may be thought desirable by means of a periodical journal, which shall be the journal of the Association, and by the occasional publication of transactions or other papers

(4) To grant sums of money out of the funds of the Association for the promotion of the medical and allied sciences in such manner as may from time to time be determined on

(5) Subject to the provisions of Section 19 of the Companies (Consolidation) Act 1908 to purchase take on lease exchange hire or otherwise acquire any real and personal property and any rights or privileges necessary or convenient for the purposes of the Association

(6) To sell improve manage develop lease mortgage dispose of turn to account or otherwise deal with all or any part of the property of the Association

(7) To borrow any moneys required for the purposes of the Association upon such terms and upon such securities as may be determined

(8) To do all such lawful things as may be incidental or conducive to the promotion or carrying out of the foregoing objects or any of them

Provided that the Association shall not support with its funds any object or endeavour to impose on or procure to be observed by its Members or others any regulation restriction or conduct which if an object of the Association would make it a trade union."

5 Clause 4 of the Memorandum of Association reads:

"The income and property of the Association, from whatever source derived, shall be applied solely towards the promotion of the objects of the Association as set forth in this Memorandum of Association, and no portion thereof shall be paid or transferred directly or indirectly by way of dividend or bonus or otherwise, by way of profit to the persons who at any time are or have been Members of the Association, or to any person claiming through any of them, provided that nothing herein shall prevent the payment in good faith of remuneration to any officers or servants of the Association, or to any Member of the Association or other person in return for any services actually rendered to the Association."

Limitation imposed by Clause 4

6 One effect of Clause 4 of the Memorandum is to prohibit the Association from making any payment from its funds to a member in order to compensate him for financial loss incurred as a result of following the Association's advice. This position was confirmed by the Opinion given by Counsel (Mr M. L. Gedge) in 1947 on the possibility of thus assisting a member who might suffer through adhering to the Association's policy on the "closed shop" issue. The following is an extract from this Opinion:

"In my opinion, the B.M.A. cannot properly afford financial assistance to its members who suffer financially as the result of following the advice of the B.M.A. not to apply for posts under authorities which attempt to enforce the 'closed shop' principle. Such assistance could not in my opinion properly be said to be 'the payment in good faith of remuneration to a member of the Association for services actually rendered to the Association' within the meaning of that expression as used in Clause 4 of the Memorandum of Association of the B.M.A., that expression applying, in my opinion, only to payment of remuneration for services actively rendered, and not to compensation for loss incurred for not adopting some particular course, and the payment would, in my opinion, be in breach of such Clause 4 as being a payment 'by way of profit' to a member."

Limitation imposed by the Proviso to Clause 3

7. To understand the restrictions imposed by the proviso to Clause 3 of the Memorandum it is necessary first to consider the nature of a trade union. For the purposes of the Trade Union Acts, 1871 to 1913, a trade union means any combination, whether temporary or permanent, the principal objects of which are under its constitution statutory objects, and these objects are defined as the regulation of the relations between workmen and masters or between workmen and workmen, or between masters and masters, or the imposing of restrictive conditions on the conduct of any trade or business, and also the provision of benefits to members.

8 In the opinion of Counsel (e.g., Mr. C. R. Havers K.C., and Mr. M. L. Gedge, 1946) members of the medical profession are neither "masters" nor "workmen," whether engaged in practice on their own account or employed by a public authority. Counsel consider, however, that medical practice, although not a "trade," would be held to be a "business" within the definition of statutory objects. Therefore the effective statutory objects which the Association could adopt are: (1) the imposition of restrictive conditions on the conduct of its members' business, and (2) the provision of benefits to members. These would have to be the principal objects under the constitution of a medical trade union. The question arises, then, as to whether the proviso to Clause 3 of the Memorandum in prohibiting the imposing of "any regulation restriction or condition which if an object of the Association would make it a trade union," debars the Association from taking such action as it might wish to take to reduce its members, or members of the profession generally, to act in accordance with its views.

9 On more than one occasion expert legal advice has been sought on this matter. Some years ago, Counsel's Opinion was taken as to what the position of the Association would be in the hypothetical event of its wishing to advise the profession at large against acceptance of contracts of service of particular kinds.

The view expressed by Counsel (Mr. C. R. Havers, K.C.) was that this would constitute an endeavour by the Association to impose on or procure to be observed by its members or others a restriction on the conduct of their business. Counsel went on to say, however, that in his opinion the imposing of restrictive conditions generally, or of this restriction in particular, was not the principal object or even one of the principal objects of the Association, but merely ancillary to one of the principal objects (the maintenance of the interests of the medical profession). He concluded, therefore, that the restriction in question, if an object of the Association, would not make it a trade union and, consequently, that the Association, if it decided to give the suggested advice to the profession at large, would not thereby be acting in any way illegally or contravening the Memorandum of Association.

10. Because of the importance of this matter, the Association sought a second Opinion from Mr. Charles Harman, K.C. (now Mr. Justice Harman). Unlike Mr. Havers, Mr. Harman drew a distinction between an endeavour by the Association to "procure to be observed by its members . . . any . . . restriction" and an endeavour to "impose on . . . its members . . . any . . . restriction." He considered that the advice in question would constitute an endeavour of the former kind but not of the latter kind, because in his view the imposing of a restriction entailed a process backed by sanctions. He then pointed out that it is the "imposing of restrictive conditions on the conduct of any . . . business" which is one of the statutory objects of a trade union. It followed that, in his opinion, the suggested advice to the profession, if adopted as an object of the Association, would not be a statutory object. He added that, even if it were a statutory object, it would not be a principal object and would therefore not make the Association a trade union. On these grounds he concluded that the suggested advice would not involve any contravention of the proviso to Clause 3 of the Association's Memorandum.

11. On a more recent occasion, when the Opinion of Counsel (Sir Cyril Radcliffe, K.C., and Mr. J. H. Stamp) was taken on another matter, the following view was expressed as to the meaning of the proviso to Clause 3: "The proviso does not, we think, propose to weigh the activities of the Association against one another and forbid trade union activities only at the point at which they outweigh its other activities, but to exclude the trade union activities altogether. The reference to trade unions is for the purpose of identifying the character of the forbidden activities; and not of limiting the exercise of an activity which, within the limit, is authorized. The intention of the proviso is to close the door entirely, and not merely to leave it ajar. Any other construction appears to reduce the proviso to a nullity."

12. It will be seen that the eminent Counsel who have been consulted are not unanimous in their views on the effect of the proviso to Clause 3 of the Memorandum of Association. But even if the view were accepted that an endeavour to impose a restriction on its members and others would not make the Association a trade union unless the restriction were a principal object, the risk would still remain that the Association could be challenged at the point by any person so disposed. Such a person might allege that, if only for a temporary period—during a major dispute with the Government, for example—the imposing of restrictions on the conduct of medical practice was a principal object of the Association, and might seek to obtain a declaration from the Court that the Association's registration as a company was void, or an injunction to restrain the Association from using its funds in contravention of its Memorandum. While such actions were *sub judice* the Association would be rendered ineffective and would be unable to take any steps in pursuance of that policy or activity which was challenged for as long as the matter was under consideration by the Courts.

Conclusion

13. After consultation with the Association's Solicitors, in the light of the views expressed in the past by Counsel, the Council has come to the conclusion that the Association, in addition to being unable to make financial grants to members who have suffered through loyalty to its policy, cannot safely bring pressure to bear upon its members to induce them to adhere to its policy. Any pressure or threat would be dangerous; and it would seem to follow that the Association cannot *organize* (although it can *advise*) concerted opposition by the profession to acceptance of service or continued acceptance of service—for example, under the

National Health Service Act. It may advise with impunity; and its advice, if supported by public opinion in the profession, may have a potent influence on the conduct of the individual member. As was pointed out by Counsel many years ago in an Opinion on the Association's ethical procedure (Mr. J. H. Stamp, 1929), "the only real and ultimate sanction for the Ethical Rules is the public opinion of the profession, involving the disapproval and ostracism by their fellow practitioners of those who disobey them."

14. It is important to observe that the disabilities discussed above are not the result of the Association not being a trade union. It is not essential for an association to be a trade union in order to secure the power to provide benefits to its members or the power, within normal limits of law, to exert pressure on its members; and, as is explained below, even a medical trade union (unlike a trade union of workmen) could not safely act otherwise than within normal limits of law. The restrictions imposed on the Association are due, not to the fact that it is not a trade union, but solely to the fact that certain practices commonly adopted by some other organizations (and typically by trade unions) are specifically prohibited by its present Memorandum of Association.

III. POSSIBLE ALTERATION OF THE ASSOCIATION'S CONSTITUTION

15. The Council has considered whether there is any way in which the Association, while continuing to exist as a company, can so alter its constitution as to remove the restrictions imposed by its present Memorandum of Association. The Solicitors, after consultation with Counsel, advise that the restrictive clauses cannot be deleted from the Memorandum so long as the Association retains its Board of Trade licence to dispense with the word "limited" in its title. A possible course, however, is to surrender this licence and then—under a provision contained in Section 5 of the Companies Act, 1948—to alter the Memorandum by special resolution so as to omit those parts which create the restrictions.

16. The alteration of the Memorandum could be arranged in this way only if, among the Association's members, the opposition to the change were very small. A minority of not less than 15% of the members could take the matter to the Court. In that case the matter would be one for the discretion of the Judge. The minority might argue that the proposed alteration of the Memorandum might thereafter, in the light of the resultant acts of the Association, imperil the validity of the Association's registration under the Companies Acts, the course of *conduct* showing that the Association, although ostensibly a company, was in fact a trade union. The Solicitors, while doubting whether this argument would succeed, point out that there would certainly be a possibility of the proposed changes of the Memorandum being rejected by the Court; and the Association would then be left with its present restrictions but without its Board of Trade licence (which, however, might be re-granted).

"British Medical Association, Limited" ?

17. If the Board of Trade licence were surrendered, and the alteration of the Memorandum achieved without or despite opposition from a section of the Association's members, what would be the advantages and disadvantages of this change in the Association's constitution? The advantages would lie in the freedom thus gained to carry on activities of a "trade union" character. The Association would no longer be restricted to the giving of advice in connexion with acceptance or non-acceptance of appointments under public authorities and other employing bodies. If, for example, circumstances arose in which the Association thought it desirable that the profession should withdraw its services under the N.H.S. Act, it could engage in a campaign of intensive propaganda and agitation throughout the country, bringing pressure to bear on the individual doctor at local meetings and through written communications, and generally stimulating and organizing concerted opposition to continued acceptance of service under the Act. Similarly, in a minor dispute affecting only a few members of the profession, the Association could use pressure to induce the doctors concerned to support its policy. It could inflict the penalty of expulsion on those of its members who had refused to conform, and it could provide financial compensation to those of its members who had suffered monetary loss through their loyalty.

For the Dyspepsias

Whenever dyspepsia with peptic ulcer or hyperchlorhydria calls for a bland but nutritious diet, Bemax should not be forgotten. Besides supplying the vitamins of the B group it contributes materially to the protein intake, and yet adds no tasty extractives or roughage to maintain undesirable gastric motility.

BEMAX supplies, weight for weight, 50% more protein than steamed cod or whiting. Its amino-acid analysis renders it of equal protein value with fish. In any regime where particular dietary care is needed, Bemax will be found to conform to the strictest requirements.

Oxford and Cambridge BOAT RACE

March 26

We have space for a few doctors and their friends to view the race from our Hammersmith Wharf Accommodation. It is limited so please make early application for tickets to Vitamins Limited (Dept. S1 A), Upper Mall, London, W.6.

The nutritional factors of Bemax are well demonstrated in the table of assay figures shown below—

VITAMINS (per oz.)	PROTEIN, MINERALS etc.
B ₁ - - 0.45 mg.	protein (first class—see*)
riboflavine 0.3 mg.	30%
nicotinic acid 1.7 mg.	carbohydrate 39%
pyridoxine 0.45 mg.	fat 8.5%
E - - 8.0 mg.	mineral salts 4.5%
	moisture 5%
	fibre - 2%

• ESSENTIAL AMINO ACIDS

	fresh weight basis	16%N basis
arginine	2.5%	8.3%
histidine	0.9%	3.0%

CASE HISTORY

L.L. Aged 42. A female Sugar Packer. Whilst at work on June 16th, 1946, she cut the outer side of her left ankle: shortly afterwards a septic eczema of the ankle area supervened. On July 26th a large clot appeared in the internal saphenous vein on the inner side of the calf (Fig. 1).

Treatment. August 9th, 1946. A well-bevelled adhesive sponge rubber pad was placed over the clot, the eczema was covered by layers of Viscopaste and the leg firmly bandaged with Elastoplast from toes to knee (Fig. 2). August 23rd, 1946. There was no pain or soreness in contrast to the presence of both before treatment. Eczema was

Fig. 2

SUPERFICIAL PHLEBITIS

Ambulatory Treatment With Elastoplast Bandaging

cleaned with calamine in oil, and dressed with Jelonet and Ichthopaste. The pressure pad was re-applied and the leg again firmly bandaged with Elastoplast.

August 30th, 1946. Treatment repeated. Sept. 27th, 1946. Clot completely disappeared, leg comfortable, eczema largely cleared up and internal saphenous vein sclerosed and obliterated (Fig. 3).

Comment. An example of ambulatory treatment of Phlebitis by local pressure over clot and firm bandaging, resulting in its speedy obliteration and in the restoration of the leg to normal condition. Details and illustrations above are of an actual case. T. J. Smith & Nephew, Ltd., Manufacturers of Elastoplast, Viscopaste, Jelonet and Ichthopaste, are privileged to publish this instance, typical of many, in which their products have been used with success, in the belief that such authentic records will be of general interest.

LOCAL ANTISEPSIS

with 'AVLON'

MILD SILVER PROTEINATE B.P.C.

Mild Silver Proteinate is well known as an effective bactericide which can be applied in solution to mucous membranes without causing irritation or damage to sensitive tissues. Its clinical uses include the treatment of ophthalmic infections, vaginitis and urethritis, infections of the nose and throat, etc. The 'Avlon' product is characterised by its relatively low hygroscopicity and ease of solubility—factors which are particularly advantageous in the preparation of solutions.

'Avlon' brand Mild Silver Proteinate is issued in containers of 25 grammes and 3 kilos.

Why Ribena in Acute Infections?

Because in acute febrile conditions such as pneumonia, diphtheria and rheumatic fever the blood vitamin-C level is markedly reduced, as is excretion of the vitamin by the kidneys.

Because it is believed that there is an important relationship between ascorbic acid and immunological reactions, as indicated, for example, in the lowering of resistance to diphtheria toxin effected by hypovitaminosis-C.

Because, on the practical side, good results are constantly being reported from the use of natural vitamin C, in the form of 'Ribena' blackcurrant syrup in rheumatic fever, scarlet fever, whooping cough, pneumonia and toxic diphtheria. More detailed information will be gladly supplied on request.

'Ribena' is the pure undiluted juice of fresh ripe blackcurrants with sugar, in the form of a delicious syrup. Being freed from all cellular structure of the fruit, it will not upset the most delicate stomach. It is particularly rich in natural vitamin C (not less than 20 mgm. per fluid ounce) and associated factors.

18. In short, the Association could pursue two of the trade union statutory objects—the imposing of restrictions on the conduct of professional “business” and the provision of benefits to members—but without the protection against legal proceedings granted by the Trade Disputes Act, 1906 (which, as is explained below, would not be afforded even if the Association were a trade union). It must be remembered, however, that these objects could lawfully be pursued only provided that they were not among the Association’s principal objects. The risk would remain that a person who wished to harm the Association might allege that the Association was in fact a trade union; and if this allegation were substantiated the Association would be wound up under the Companies Acts.

19. The disadvantages of the suggested change in the Association’s status are by no means negligible. Although it would no longer be necessary to observe the formality of submitting proposed alterations of the Articles to the Board of Trade for approval, it would become necessary to make returns of the Association’s accounts in accordance with the provisions of company law. The Solicitors think it probable that the Association would cease to enjoy its present immunity from payment of income tax, and this might seriously affect its financial position. Finally, the Association would be obliged to use the title “British Medical Association, Limited.” There is involved here the prestige of the Association as the chief representative organization of a learned profession, and one concerned with important scientific and ethical matters apart from its medico-political functions. It would no longer be possible, for example, for the Association to enjoy the patronage of the King. For these reasons it appears desirable to consider whether another form of organization could not protect the interests of the profession no less effectively than could the Association with the changed constitution here discussed.

Conversion to a Trade Union?

20. It has been suggested from time to time that the restrictions imposed on the Association by its present constitution would be removed if the Association acquired the status of a trade union. The fact is that the conversion of the Association into a trade union is impossible. The Association is a company incorporated under the Companies Acts, 1862 and 1867, and it is laid down in the Trade Union Act, 1871, that these Acts, among others, “shall not apply to any trade union, and the registration of any trade union under any of the said Acts shall be void.”

21. Although the Association, while it remains a company registered under the Companies Acts, cannot be registered as a trade union, it is possible for the Association to be wound up and for its members, or such of them as might so wish, to form themselves into a new Association and seek to register the new body under the Trade Union Acts. Apart from other objections to terminating the existence of the Association, there is a special difficulty in that, in the opinion of Counsel (Mr. C. R. Havers, K.C., and Mr. M. L. Gedge, 1946) it would be impossible to transfer the assets of the Association to the new body, these assets in a winding up of the Association belonging to its members. The Council therefore does not regard this course as a practicable one.

22. Another possibility is for the Association to continue to exist for its present purposes and for a new organization to undertake such functions as are connected with the imposing of restrictions on the conduct of medical practice, and for this new organization to seek registration as a trade union. This possibility is discussed below; but in view of the commonly expressed desire that the Association itself should become a trade union, it may be appropriate to state here that this change in the Association’s status, if it were practicable, would by no means have all the advantages imagined by its advocates. The matter is explained clearly in an Opinion obtained from Counsel—Mr. F. Gore Browne, K.C., and Mr. H. H. Slessor (later Lord Justice Slessor)—in 1919, after substantial damages had been awarded against the Association in an action resulting from ethical proceedings against certain practitioners employed by the Coventry Dispensary on terms and conditions held by the Association to be contrary to the best interests of the profession. This Opinion is summarized in the two following paragraphs.

23. Those who advocate the registration of the Association as a trade union no doubt look mainly to the protection offered by the Trade Disputes Act, 1906, and particularly to Sections 3 and 4

of this Act. Section 3 provides that an act done by a person in furtherance of a “trade dispute” shall not be actionable on the ground only that it interferes with another person’s business, etc.; and Section 4 provides that an action against a trade union, whether of workmen or masters, in respect of any tortious act alleged to have been committed by or on behalf of the trade union, shall not be entertained by any court. In short, these Sections afford immunity from legal proceedings in respect of certain acts which ordinarily would be actionable wrongs, provided that these acts are committed in furtherance of a trade dispute or committed by or on behalf of a trade union.

24. It is to be noted, however, that the expression “trade dispute” is defined in the Act as meaning a dispute (connected with employment) “between employers and workmen or between workmen and workmen”; and that the expression “workmen” is defined as meaning “all persons employed in trade or industry.” Now, in the opinion of Counsel, a medical practitioner is not “employed in trade or industry” and is not a “workman” within the meaning of the Act; and it follows that, unlike a trade union of workmen, a trade union composed of medical practitioners could derive no benefit from Section 3 of the Act. It is to be observed also that Section 4 deals only with “an action against a trade union, whether of workmen or masters.” The opinion of Counsel is that medical practitioners are neither workmen nor masters within the meaning of the Act, and that Section 4 would not be extended so as to give protection to a medical trade union. “It must be remembered,” Counsel state, “that the Section, in removing from the jurisdiction of the Courts in regard to wrongful acts a section of the community, will be read strictly.” It appears, then, that the widely held opinion that the conversion of the Association into a trade union, were this practicable, would place it in a peculiarly strong position is without solid foundation so far as it rests on the supposed protection of the Trade Disputes Act, 1906, which offers real advantages to a trade union of “workmen” but not to a trade union of medical practitioners.

Conversion to a Friendly Society?

25. The Council is advised by the Solicitors that conversion of the Association into a friendly society, like conversion into a trade union, is impracticable. This again would involve the winding up of the Association and the distribution of its assets among its members.

IV. POSSIBLE FORMATION OF A PARALLEL ORGANIZATION

26. The alternative to the alteration of the Association’s constitution is the creation of a new organization, free from the restrictions imposed on the Association, and so closely linked with the Association that the policies of the Association and of the new organization would always be parallel. The Council has considered, in particular, the advisability of establishing such a parallel organization in the form of a trade union.

A Parallel Trade Union

27. It is clear, in the first place, that a parallel trade union could not achieve the desired results unless it were in a position to protect the Association’s membership generally. A trade union which attracted to its membership only a proportion of the Association’s members would be of no value. While it could advise the whole profession, it would have powers of compulsion only over its own members and it could provide benefits only to its own members. The ideal arrangement would be one under which membership of the Association was conditional on membership of the trade union and vice versa. Unfortunately, this ideal is unattainable. The difficulty is explained in the following statement received from the Association’s Solicitors:

“We think the test to be applied is this: suppose the new organization passed some policy resolution which the Association was precluded by its constitution from doing: for example, a resolution that no member should participate in the National Health Service. The new organization could expel from membership any member disobeying this policy resolution: if it were as suggested a condition of membership of the Association that its members should also be members of the new organization, then expulsion from the new organization would also mean the cessation of membership of the Association: in other words, a practitioner would cease to be a member of the Association because he failed

to comply with a policy resolution which the Association was expressly precluded by its constitution from enforcing. We think this makes it apparent that it would not be possible for the B.M.A. to introduce this new condition of membership."

28. On the other hand, the Solicitors state that it would be possible to make it a condition of membership of the parallel trade union (or other new organization) that the applicant should be a member of the Association. This, however, would not ensure that the membership of the trade union would largely correspond with that of the Association. The difficulty cannot be dismissed by stating that, if a considerable section of the profession did not see fit to join the trade union, these practitioners would have only themselves to blame for the fact that they could not enjoy the benefits of membership. The important consideration is that a trade union unable to provide pecuniary benefits to a large majority of the profession could not effectively organize collective action.

29. Apart from this problem of membership, what would be the advantages and disadvantages of a trade union as the parallel organization, as compared with other forms of organization such as an independent body of trustees controlling a "fighting fund"? The Solicitors advise that the only real advantage would lie in certain income tax exemptions granted to trade unions. As has been explained above, a medical trade union would not enjoy the protection of the Trade Disputes Act, 1906. The Solicitors advise that in the organization and enforcement of collective action a medical trade union would be no more effective than a body with a different form of constitution. Even if they were lawful in the case of a medical trade union, the activities of calling a strike and arranging picketing to prevent "blacklegging" are not such as would commend themselves to the medical profession; and it is questionable whether the profession, opposed as it is to the "closed shop" policy, would favour the exertion of pressure on medical practitioners by a threat of expulsion from a medical trade union as a means of depriving them of opportunities of employment.

30. In 1946 the Opinion of Counsel (Mr. C. R. Havers, K.C., and Mr. M. L. Gedge) was again taken on the advantages and disadvantages of setting up a medical trade union. They advised that the main advantage was that, if local or other public authorities made it a condition of employment that a member of the medical profession must be a member of a trade union, then there would be a trade union "ready made" for such a member to join. "The disadvantages as we see them," they wrote, "are all of a practical nature. We were informed in consultation that many members of the Association might object to the formation of a medical trade union, while in any event the formation of a separate entity must tend towards creation of a divided allegiance and thus be harmful to the Association. Registration as a trade union would also involve compliance with statutory provisions which might be distasteful—e.g., the submission to the Registrar of annual statements of receipts, funds, effects, and expenditure; and on balance our view is that, unless the advantage of having a trade union available for members to join would outweigh the practical disadvantages, no such union should be formed."

31. The Council has not omitted to take note of the view, held by many members of the profession, that there is virtue in the trade union designation, however limited the actual powers of a medical trade union might be. The argument is that a professional organization, merely by being constituted as a trade union, would more readily influence one or another form of Government in its favour. On this matter the opinion of the Council is that success in negotiation depends less on the form of the negotiating body than on the cohesion of an overwhelming majority of its members in determined support of its policy. The Council is not convinced that, in the case of a medical body, the trade union label would materially facilitate the process of negotiation; and it has had primarily in mind the question of what form of organization could most effectively pursue the aims of the profession when attempts at negotiation had had unsatisfactory results, as might well happen even if the negotiating body were registered under the Trade Union Acts. Regarding this matter from this point of view, it has reached the conclusion that there are no substantial advantages in the trade union form of organization as compared with other possible types of constitution. It thinks, however, that, should it be decided to set up a parallel organization in another form, it would be well so to frame its constitution and powers that, if at a future date a trade union seemed desirable because of a change in the situation or an enlargement of trade union powers, the

new organization could be reconstituted as a trade union or its funds transferred to a trade union.

Other Types of Parallel Organization

32. The other possible types of organization which the Council has considered are a friendly society, an unincorporated association, a limited liability company, and a board of trustees which would act in much the same capacity as the governing body of a trade union or other organization. The Solicitors advise that the first three have no positive advantages peculiar to themselves as alternatives to a trade union and accordingly the Council has discussed only the last. A parallel organization in the form of a board of trustees would in no way usurp the functions of the Association in connexion with the framing of policy in relation to medico-political issues. The Representative Body would continue as at present, to determine policy, and the Council would continue to take all lawful steps to carry out the policy so determined. The board of trustees would come into action only when, in pursuance of this policy, measures were called for such as the Association is precluded from undertaking because of the limitations of its constitution. There would thus be no question of any conflict of policy between the Association and a new body in the form here discussed. Indeed, the new organization would not be a "body" at all in the sense of an association which individual medical practitioners could join as "members." It follows that the board of trustees would not have at their disposal the sanction of expulsion vested in, for example, the governing body of a trade union, but it is felt that sanctions imposed by the constitution of the organization under consideration are not of great practical importance in view of the difficulties and dangers of their use in times of dispute, as indicated by the Coventry case and many others which have come before the Courts. It should again be stressed that the effectiveness as a sanction of expulsion from a working men's trade union lies not in the expulsion itself but in the fact that it brings in its train such grave consequences as prohibition of employment in "closed shop" works and the like, consequences which can safely be imposed by working men's trade unions because of the Trade Disputes Act, 1906, but not by an organization of medical practitioners. In practice the enforcement of sanctions depends on medical opinion. Unless the trustees speak with the voice of the medical profession their policy cannot be enforced in any case; and if they do, then public opinion within the profession will bring back-sliders into line more quickly and effectively than anything else.

V. SUMMARY AND CONCLUSION

33. After careful consideration of all the arguments the Council has come to the conclusion that the best course is to leave the Association's present constitution unchanged and to set up a parallel organization. The whole matter may be summarized briefly as follows:

1. For the protection of the interests of the profession in conflicts with public authorities and other bodies it is essential that there should be in existence an organization which, so far as is lawful, can exert pressure on members of the profession to induce them to adhere to the policy favoured by the majority, and can also compensate them for financial loss incurred through loyal acceptance of such policy.

2. As constituted at present, the Association is not in a position fully to perform these functions; for Clause 4 of its Memorandum of Association expressly prohibits the payment of pecuniary benefits to its members, and although expert opinions differ as to the precise interpretation of the proviso to Clause 3, eminent legal authorities have expressed the view that it entirely precludes the imposing of restrictions on the conduct of medical practice, and it is therefore clear that the Association cannot safely exert pressure on members of the profession in disputes of the kind contemplated.

3. The Association suffers from these restrictions solely because they are imposed upon it by its Memorandum, and not because the Association is not registered as a trade union; for it is by no means only a trade union that is entitled to express views as to the interests of its members and to seek to enforce its views.

4. It is possible that the Association, after surrendering its Board of Trade licence to dispense with the word "limited"

in its title, could remove the restrictive clauses from its Memorandum; but there would be serious disadvantages in the surrender of the licence, including probably the loss of the Association's present immunity from payment of income tax and certainly a lowering of its prestige in the professional world.

5. Alternatively, the Association could be wound up and a new body, free from its present restrictions, formed to replace it; but, if only because the assets of the Association could not be transferred to the new body but would have to be distributed to its members, this course is not one that can be considered practicable.

6. There remains the possibility of leaving the Association's present constitution unchanged and setting up a parallel organization with supplementary functions connected with the enforcement of collective action in medico-political disputes and the provision of financial compensation for pecuniary loss incurred by individual members of the profession through participation in such collective action.

7. This parallel organization could be established in the form of a trade union, but the advantages of this form of organization would be limited, and would not (as is commonly but erroneously supposed) include the protection of the Trade Disputes Act, 1906; while, on the other hand, there might be some disadvantages, including an apparent inconsistency in the Association sponsoring a medical trade union, opposed as it is to certain trade union policies such as that of the "closed shop."

8. The form of independent parallel organization which appears to deserve consideration is a board of trustees who would act in much the same capacity as the governing body of a trade union and, within normal limits of law but without the limitations of the Association's constitution, could seek to impose restrictions on the conduct of medical practice and organize collective resistance in disputes with public or other authorities; and the establishment of an organization of this kind seems to be the method of securing the desired result which involves the least disadvantage.

34. The organization proposed by the Council would act both major disputes and in minor emergencies affecting individuals. It is not suggested that, in building up its finances, it should encroach in any way on the province of the National Insurance Efficiency Trust, which would continue to collect financial contributions from general practitioners for use at the discretion of its trustees; but the establishment of the new organization would provide the necessary opportunity for all other branches of the profession to make similar contributions. If it were decided to set up an organization of the kind recommended, it would be essential to secure a steady flow of subscriptions in advance of disputes, so as to avoid the necessity of an emergency appeal on the occurrence of a crisis. One possibility is that the Association could collect contributions to the new organization when collecting its own subscriptions from its members. The Solicitors have advised that this procedure, although it would not be permissible if the parallel body were a trade union, might be possible in the case of an organization of the kind proposed by the Council, provided that the administrative expenses incurred by the Association were reimbursed. Other matters which call for exploration are the part which could properly be played by the *British Medical Journal* in connexion with the activities of the proposed board of trustees, and the kind of peripheral organization necessary to secure local compliance with the policy of the board. The Council has these matters under consideration.

35. The Council suggests that the new organization should be known as the British Medical Guild. Appended to this Report is a Trust Deed prepared by the Solicitors, in consultation with Counsel.

VI. RECOMMENDATION

36. With reference to Minute 65 of the A.R.M., 1948, the Council recommends:

(1) that, for the better protection of the interests of the medical profession in disputes with public authorities and other bodies, a new organization be established in the form of an independent board of trustees with power to organize and finance collective action by the profession and to provide financial compensation to practitioners suffering financial hardship through participation in such collective action;

(2) that the new organization be entitled the British Medical Guild;

(3) that the new organization be constituted in accordance with the Trust Deed as drafted by the Association's Solicitors.

APPENDIX

THIS DECLARATION OF TRUST is made the
day of 1949 BETWEEN*

of of and
of the one
part and BRITISH MEDICAL ASSOCIATION whose registered
office is at British Medical Association House Tavistock Square
in the County of London (hereinafter called the Association) of
the other part

WHEREAS a sum of (£500) has been placed by certain donors in the hands of the Association to form the nucleus of a fund to be held on trusts concerning the same which are to be declared by the parties hereto of the first part and the said parties now desire to declare the trusts following in respect of the same and of any other sums of money or property which may hereafter be added thereto

NOW THIS DEED WITNESSES:—

1. THE said sum of (£500) and all other money and property which shall from time to time be subject to the trusts hereof are hereinafter called the Trust Fund.

2. THE Trust Fund shall be known as the British Medical Guild.

3. THE Trust Fund and the income thereof shall be held by the Association or other the trustee or trustees for the time being hereof upon trust to give effect to any directions of the Board of Trustees hereinafter referred to (hereinafter called the Board) which may be lawful and consistent with the provisions hereof and the Association shall not be liable for breach of trust in respect of any act done by it in pursuance or bona fide purported pursuance of any such direction.

4. THE objects to which the Board may direct the application of the capital and income of the Trust Fund (in addition to defraying the costs of administering the trusts hereof) are as follows:—

(i) During a period consisting of the lifetime of the longest liver of the issue now living of His Majesty King Edward the Seventh and 21 years thereafter

(a) The taking of action to acquire or appeal for additional money and property to be added to the Trust Fund:

(b) The taking of such action as the Board from time to time consider expedient in the interests of the Medical Profession or any section or sections of such profession:

(c) The giving of financial assistance to or for the benefit of any registered medical practitioner or class or classes of registered medical practitioners who at any time during such period may appear to the Board to have suffered or be likely to suffer hardship as a consequence of his or their loyalty to any policy sponsored or approved by the Board with reference to the affairs of the Medical Profession:

(d) The making of payments by way of distribution to persons who shall appear to the Board to have subscribed to the Trust Fund of any sum or sums appearing at any time and from time to time to the Board not to be required for the foregoing purposes or any of them such distribution or distributions to be in such proportions among the recipients as the Board shall in their uncontrolled discretion think just and equitable.

(ii) From and after the conclusion of such period such charitable objects as the Board may think fit being charitable objects connected with the Medical Profession and in particular such (if any) of the objects to which the Trust Fund or the income thereof are applicable during the said period as are charitable objects

PROVIDED ALWAYS that no person or body shall during the said period be entitled by reason of having subscribed to the Trust Fund or otherwise to question any exercise by the Board of their discretion to direct the application or distribution of the

*These will be the present members of the Council

Trust Fund or any part thereof and the income thereof or any part thereof except on the ground of fraud or bad faith.

5. THE giving of assistance to or for the benefit of registered medical practitioners or any class or classes of them shall be deemed to include the giving of like assistance to any parent wife husband widow widower child or issue of any such registered medical practitioner living or dead or to any person appearing to the Board to be or to have been a dependent of any such registered medical practitioner living or dead and the Board may direct payment to any person corporation or unincorporated body who or which seems to the Board to be a proper recipient of any sum the application of which they direct under this clause and the receipt of any such person or corporation (by its proper officer) or unincorporated body (by its Treasurer or other proper officer) shall be an absolute discharge to the Association in respect of such payment.

6. THE power of appointing new trustees hereof in place of the Association or any successor of the Association is vested in the Board. The expression "the Association" used herein means and includes (where the context does not otherwise require) British Medical Association and other the trustees or trustee for the time being hereof.

7. THE management of the Trust Fund shall be vested in the Board. The parties hereto of the first part shall be the first members of the Board and hereafter the members of the Board for the time being shall be the persons who from time to time are the members of the Council of the Association. Members of the Board shall enter and vacate office as such without any formality as a consequence of their entering or vacating office as members of such Council provided however

(i) that for the purposes hereof no member of the Board (other than the parties hereto of the first part) shall be entitled to act unless and until the Secretary of the Association shall have informed the Board or their Secretary in writing of his appointment as a member of the said Council and until such member of the Board has also executed a written statement (which shall normally be in the Board's Minute Book) that he has accepted office as a member of the Board; and

(ii) that no member of the Board shall be discharged from his office as such until the Secretary of the Association has given like written information of his ceasing to be a member of the said Council.

8. NOT less than two thirds of the members of the Board in office at the date of the dissolution of the Association may by deed make other provision for the appointment of members of the Board in place of the provisions of the foregoing clause hereof.

9. THE Board shall appoint a Secretary and any other office or servants whose employment seems to them expedient.

10. THE Board may act by resolutions passed by a majority of those present and voting at a meeting of the Board (except where by this deed they are required to act in some other way) and a written certificate of the Secretary to the Board stating the terms of any resolution of the Board shall be conclusive evidence to persons (including the Association) dealing with the Board both of the terms of such resolution and of the fact that it was duly passed.

11. THE Board may regulate their own procedure by means of standing orders passed by them as resolutions and unless at any time they make any standing order to the contrary they shall be deemed to have adopted (mutatis mutandis) the standing orders of the Council of the Association.

12. THE Board may make regulations not inconsistent herewith for the conduct of the Trust Fund and may from time to time alter and revoke the same and any of them.

13. THE Trust Fund may be invested or applied in the purchase of or in lending on the security of any form of property whatsoever or wheresoever and whether or not authorised by law for the investment of trust funds as if the Association were an individual entitled thereto beneficially or in making loans on personal security to any person to whom or for whose benefit financial assistance may under the provisions hereof be given out of the trust fund or the income thereof.

14. WITHOUT prejudice to the generality of any other provision hereof any act done or omitted by the Board or the Association upon the advice of a member of the English Bar (not less than 15 years standing shall (unless such act is proved to have been done or omitted in bad faith) not give rise to any liability of the Board or the Association as the case may be) in breach of trust whether or not such advice is correct in law.

15. THE Auditors of the Association or other auditors from time to time appointed by the Board shall audit the accounts of the Trust Fund yearly and shall make a report to the Board on behalf of the Association.

16. IN the event of the dissolution of the Association the Board may adapt the provisions of this deed (other than the matters dealt with in Clauses 7 and 8 hereof) so as to ensure the continuance so far as practicable of the work of the British Medical Guild and such adaptation may be made by resolution. Provide however that nothing in this clause enables the Board to prescribe any trusts of the Trust Fund other than charitable trusts in respect of any time after the expiration of the period referred to in paragraph (i) of Clause 4 hereof.

IN WITNESS, etc.

ONE HUNDRED AND SEVENTEENTH ANNUAL MEETING, HARROGATE, JUNE 24 TO JULY 1, 1949

President-Elect: C. W. CURTIS BAIN, M.C., D.M., F.R.C.P., Senior Physician, Harrogate General Hospital

PROVISIONAL PROGRAMME

For the Annual Meeting at Harrogate the programme of scientific meetings and social events is almost complete, as will be seen from the information following. A longer period is devoted to the scientific meetings, which should prove of exceptional interest. On the social side a very full programme has been drawn up, including numerous excursions to places of interest in the neighbourhood, civic receptions, dances, theatres, concerts, and every kind of sport. It is hoped that the programme so arranged will provide suitable entertainment for visitors and make the meetings successful and enjoyable.

The Annual Representative Meeting will begin at the Royal Hall, Harrogate, on Friday, June 24, at 10 a.m., continuing all day on Saturday and Monday and, if necessary, on Tuesday morning.

The Representatives' Dinner will take place at 7.30 p.m. on Monday, June 27, at the Grand Hotel, and it will be

followed at 9 p.m. by the Statutory Annual General Meeting, which will be held in the Ballroom of the Grand Hotel. The adjourned Annual General Meeting and President's Address will take place in the Royal Hall on Tuesday, June 28, at 8.30 p.m., followed by the President's Reception in the Lounge Hall.

The Annual Dinner of the Association will take place on Thursday, June 30, at 7.30 p.m. in the Majestic Hotel. It is hoped to hold a Civic Reception in the Royal Hall on Friday, July 1, at 8.30 p.m.

The Official Religious Service will be held in St. Peter's Church at 3 p.m. on Tuesday, June 28, and Catholic Benediction will be held in St. Joseph's Church at 3 p.m. on Thursday, June 30.

The Reception Room for registration, in the Sun Pavilion, will be opened on Monday, June 27, at 2 p.m. The Ladies' Club will be at the Prospect Hotel

The Annual Exhibition of Surgical Appliances, Foods, Drugs, and Books will be housed in the Sun Pavilion. The official opening will take place on Tuesday, June 28 at 9 a.m., it will remain open on June 29 and 30 and July 1 from 9 a.m. to 6 p.m.

The Pathological Museum in the Royal Bath Hospital, Cornwall Road, will be opened on Tuesday, June 28, at 9.30 a.m. and will remain open for the rest of the Meeting. It is hoped to hold a Civil Reception in the Royal Hall on Wednesday evening June 29.

The Local Division hopes to hold a Garden Party on Thursday afternoon June 30 at the Majestic Hotel.

The President-Elect has kindly offered to give a cocktail party at his house for the Representatives on Thursday evening, June 23.

There will also be a Concert for the Representatives in the Royal Hall on Sunday evening, June 26.

The usual Golf and Chess Competitions will be held.

VISITS AND EXCURSIONS

There are within easy reach of Harrogate a number of places of historic and scenic attraction. An opportunity will be given for those attending the Annual Meeting of the British Medical Association to see the Yorkshire countryside and to visit places of special interest.

Foremost among these is Fountains Abbey, the best-preserved of the Cistercian abbeys in Britain. Adjacent to the Abbey is Fountains Hall, a Jacobean dwelling which has recently been converted into a museum containing original charters relating to the Abbey and a number of other interesting exhibits. Rievaulx, Bylands, Jervaulx and Bolton are other abbeys set in surroundings of great beauty to which visits have been arranged.

A short distance from Fountains Abbey is Ripon, a cathedral city full of historic associations and the last to preserve the age-old custom of curfew sounded by a horn. Arrangements have been made for a civic reception by the city authorities, and it is hoped to show delegates much of interest in this ancient town. Yorkshire dales are well renowned and coach tours will carry the visitors through Wharfedale, Swaledale, Wensleydale, and Nidderdale, affording views of the wild and rugged Yorkshire moorland scenery.

It is hoped also to arrange excursions to the grounds and park of the Harewood estate.

A visit will be paid to Ripley Castle with its Cromwellian associations. Three miles away and also connected with Cromwell, is the township of Knaresborough with its ancient castle and dungeon the old market place with its quaint setting, and many other features of archaeological interest.

The City of York, with its magnificent Minster, its Roman wall, and its many museums will be the venue of several excursions, visits have been arranged which it is hoped will give an insight into the attractiveness and charm of this ancient city.

A special excursion is also being arranged to the Bronte country, and those who visit Haworth will see the background of this strange family of genius.

A visit of great interest is that to Temple Newsam the "Templestowe" of *Ivanhoe* and the birthplace of Lord Darnley, husband and cousin of Mary, Queen of Scots now used as an art gallery and museum by the City of Leeds.

HOTEL AND LODGING ACCOMMODATION

Harrogate is fortunately placed as regards hotel and other accommodation to suit every requirement. No booking of accommodation for members will be undertaken by the B.M.A. other than for overseas guests. Members intending to be present at the Meeting are strongly advised to make their arrangements at a very early date, as hotel and boarding-house accommodation becomes very fully booked up for the season.

To assist members in making their arrangements a list of hotels is given below. The rates quoted are not guaranteed but are those published up to date. In order to benefit from

the special conference terms every member should mention when applying that he is attending the B.M.A. Conference.

SCIENTIFIC SECTIONS

The clinical and scientific work will be divided among eighteen Sections meeting on Tuesday, Wednesday, Thursday and Friday, June 28, 29, and 30 and July 1.

The Sections will meet in various hotels (see programme). Please note that it has been necessary to make some alterations in the original programme and therefore the following Sections will be meeting in different hotels from those specified in the B.M.A. brochure sent out in January.

Section	Hotel
Anaesthetics	Queen (not Prince of Wales)
Neurology and Psychiatry	Majestic (not Grand)
Ophthalmology	Prince of Wales (not Majestic)
Radiology	Queen (not Majestic)
Anatomy and Physiology	Carm Hydro and Prince of Wales
Otorhinolaryngology	Carm Hydro (not Prince of Wales)

There have also been some alterations in the number of days some Sections will be meeting—e.g., Radiology is a four-day (not a two-day) Section, Anatomy and Physiology, Cardiology, Dermatology, and Occupational Health are all now two-day

(not one-day) Sections. In fact, there are now no one-day Sections.

Below is a list of the names of the Sections and the officers appointed to each, together with provisional programmes.

The following Sections will meet on Four Days :

MEDICINE

President : Professor R. E. TUNBRIDGE, O.B.E., M.Sc., M.D., F.R.C.P. (Leeds).

Vice-Presidents : R. R. BOMFORD, D.M., F.R.C.P. (London); Professor H. W. FULLERTON, M.D., M.R.C.P. (Aberdeen); Professor A. P. THOMSON, M.C., M.D., F.R.C.P. (Birmingham).

Hon. Secretaries : T. G. REAH, M.D., M.R.C.P., 4, Spring Grove, Harrogate; J. L. LOVIBOND, M.D., F.R.C.P., 81, Harley Street, W.1.

Meeting-place : Harrogate Hydro.

The following programme has been arranged :

Tuesday, June 28.—10 a.m., *Discussion* : Diabetes Mellitus. To be opened by Dr. R. D. LAWRENCE (London), followed by Professor R. E. TUNBRIDGE (Leeds), Insulin and Diet; Mr. H. H. FOURACRE BARNES (London) and Dr. CHARLES ROLLAND (Edinburgh), Pregnancy Aspects; Mr. D. A. HALL, Ph.D. (Leeds), Rapid Blood Sugar Estimations; Dr. R. G. PALEY (Leeds), Skin Complications of Insulin Injections; and Dr. A. J. BALLANTYNE (Glasgow), Ocular Complications.

Wednesday, June 29 (Combined Meeting with Section of Surgery).—10 a.m., *Discussion* : Treatment of Peptic Ulcers. To be introduced and summarized by Sir HENRY COHEN (Liverpool) and opened by Mr. A. HEDLEY VISICK (York), followed by Dr. RICHARD DOLL (London), Sociological Aspects; and Mr. A. D. BEATTIE (Leicester), Surgical Aspect.

Thursday, June 30.—10 a.m., *Papers* : (1) Radioactive Substances in Clinical Medicine, by Dr. RUSSELL FRASER (London); (2) Anticoagulants, by Professor H. W. FULLERTON (Aberdeen); (3) Streptomycin, by Dr. GEOFFREY MARSHALL (London).

Friday, July 1.—10 a.m., *Discussion* : Cirrhosis of the Liver. To be opened by Professor J. W. MCNEE (Glasgow), followed by Dr. N. H. MARTIN (London), Pathology; Mr. J. E. RICHARDSON (London), Surgical Aspects; and Dr. E. R. CULLINAN (London), Summary.

Thursday, June 30, and Friday, July 1.—2.30 p.m., Royal Bath Hospital. *Demonstration* : The Role of Surgery in Rheumatism. "Movement is Life" (Lucas-Championnière).

OBSTETRICS AND GYNAECOLOGY

President : Professor A. M. CLAYE, M.D., F.R.C.S., F.R.C.O.G. (Leeds).

Vice-Presidents : GLADYS KAY, M.D. (Harrogate); Professor T. N. A. JEFFCOATE, M.D., F.R.C.S.Ed., F.R.C.O.G. (Liverpool); ARNOLD L. WALKER, M.B., F.R.C.S., F.R.C.O.G. (London).

Hon. Secretaries : C. RUTHERFORD MORISON, M.D., M.R.C.O.G., 2, Lancaster Road, Harrogate; Miss JOSEPHINE BARNES, D.M., F.R.C.S., M.R.C.P., M.R.C.O.G., 7, Wimpole Street, W.1.

Meeting-place : Prince of Wales Hotel.

The following programme has been arranged :

Tuesday, June 28.—10 a.m., *Discussion* : Breech Presentation and its Management. To be opened by Mr. R. NEWTON (Manchester), followed by Mr. C. M. MARSHALL (Liverpool), Mr. B. L. JAFFERSON (Leeds), and others.

Wednesday, June 29 (Combined Meeting with Section of Radiology).—10 a.m., *Discussion* : The Value of X-ray in Assessing Disproportion. To be opened by Professor CHASSAR MOIR (Oxford) and Dr. J. BLAIR HARTLEY (Manchester), followed by Miss MEAVE KENNY (London) and others.

Thursday, June 30 (Combined Meeting with Section of Dermatology).—10 a.m., *Discussion* : Pruritus Vulvae. To be opened by Professor T. N. A. JEFFCOATE (Liverpool) and Dr. G. A. GRANT PETERLIN (Edinburgh), followed by Dr. ELIZABETH HUNT (London).

Friday, July 1.—10 a.m., *Discussion* : Functional Uterine Haemorrhage. To be opened by Mr. V. B. GREEN-ARMYtage (London), followed by Dr. P. M. F. BISHOP (London) and Dr. T. N. MACGREGOR (Edinburgh).

PATHOLOGY AND BACTERIOLOGY

President : Professor R. J. V. PULVERTAFT, M.D., F.R.C.P. (London).

Vice-Presidents : Professor T. F. HEWER, M.D., F.R.C.P. (Bristol); J. G. GREENFIELD, M.D., F.R.C.P. (London); A. H. T. ROBB-SMITH, M.D., M.R.C.P. (Oxford).

Hon. Secretaries : J. V. WILSON, M.D., M.R.C.P., Harrogate General Hospital, Harrogate; Professor H. A. MAGNUS, M.D., Department of Pathology, King's College Hospital, Denmark Hill, S.E.5.

Meeting-place : Grand Hotel.

The following programme has been arranged :

Tuesday, June 28.—10 a.m., *Discussion* : The Laboratory Diagnosis and Prevention of Whooping-cough. To be opened by Professor R. CRUICKSHANK (London), followed by Dr. W. C. COCKBURN (London) and Dr. D. G. EVANS (Manchester).

Wednesday, June 29 (Combined Meeting with Section of Tropical Medicine).—10 a.m., *Discussion* : Fat Metabolism and the Sprue Syndrome. To be opened by Professor A. C. FRAZER (Birmingham), followed by Dr. DOUGLAS BLACK (Manchester), Dr. K. D. KEELE (London), and others.

Thursday, June 30.—10 a.m., *Discussion* : Chemotherapy in the Treatment of Malignant Disease. To be opened by Professor E. C. DODDS (London), followed by Sir STANFORD CARR (London), Professor A. HADDOW (London), and Professor F. DICKENS (London).

Friday, July 1.—(Subjects and speakers to be arranged.)

RADIOLOGY

President : J. L. A. GROUT, F.R.C.S.Ed., D.M.R.E., F.F.R. (Sheffield).

Vice-Presidents : C. G. HITCHCOCK, M.R.C.S., L.R.C.P. (Harrogate); J. ALEX. THOMSON, M.B., Ch.B., D.M.R.E. (Harrogate); Professor BRIAN W. WINDEYER, F.R.C.S.Ed. D.M.R.E., F.F.R. (London).

Hon. Secretaries : C. N. PULVERTAFT, M.B., B.Ch., D.M.R.E. York County Hospital, York; JOHN R. NUTTALL, M.D., F.F.R. D.M.R., Radium Department, General Infirmary, Leeds.

GENERAL MEDICAL SERVICES COMMITTEE

A meeting of the General Medical Services Committee was held on Feb. 17, with Dr. S. Wand in the chair. The committee faced a formidable agenda, more than enough for the entire day which it devoted to the meeting, and it was agreed that the Executive Subcommittee already existing should be enlarged up to 11 members, and in addition to considering matters referred to it by the main committee should deal with matters of urgency in the intervals between sessions.

The chairman stated that the Ministry desired to settle to the end of the current financial year (March 31) the sum which should go to each executive council for the nine months. In spite of all attempts to avoid it there had been inflation of lists and areas which had been careful in this respect were likely to be in a less favourable position than areas which had not. The suggestion of the Ministry was that the number of persons in an executive council area who had signed on should be taken, and one-third of the difference between such number and the total population should be added, giving the basic figure for the computation of the pool, and that the maximum should be 98, so that any area which showed a higher figure would be brought down to that level.

Some discussion took place on the accuracy of estimates of the total population and whether ration cards would not offer a more reliable method than the Registrar-General's computation, but the committee agreed to accept the 98% proposal as a temporary arrangement for the nine months and to set up a subcommittee of four to investigate deflation of lists or, in other words, the accuracy of lists in relation to population.

Training Grants for Assistants

The method of apportionment of grant as between principal and assistant has been explained in a statement issued by the Ministry to all executive councils. A motion from Cheshire was before the committee to the effect that the scheme as at present constituted was open to grave abuse and ought to be remodelled, and that a committee of investigation ought to be set up to consider the suitability of practitioners for accepting assistants as trainees.

Experiences were exchanged among members of the committee, especially on the practice of local medical committees in determining the eligibility of practitioners to participate in the scheme and the value of representation of the universities. It was stated that in some areas most of the applications for assistants were from principals who were compelled either to "shed" patients or to take an assistant, and that such principals could hardly have time to devote to training. A county was mentioned in which an application had been received from a practitioner with a list of 6,000. Some guidance was necessary to ensure that local medical committees worked on uniform principles.

It was agreed to set up a small special committee to consider this matter and, as it was desired to get the university point of view to ask Sir Henry Cohen, chairman of the special B.M.A. Committee on Postgraduate Education, to be a member of it, the other members being Dr. J. B. Bennett (chairman), Dr. A. T. Rogers, Dr. W. D. Steel, Dr. S. A. Winstanley, and Dr. W. Woolley. The Minister's "guidance" circular was approved provisionally and pending the report of this committee.

Legal Representation before Medical Service Committees

Dr. R. Forbes, secretary of the Medical Defence Union, attended in support of a letter which the Union had addressed to the committee drawing attention to the desirability that practitioners appearing before medical service committees should have the right to have legal assistance. He said that it had been the policy of the late Insurance Acts Committee that legal representation should be given neither to respondent nor to complainant, but as a result of changes this policy ought to be reviewed. Practitioners were now dealing with a class of patients likely to be more litigious, and an increasing number of doctors were being arraigned on alleged breaches of terms of service closely akin to negligence. If these doctors appeared without legal assistance some of them through unfamiliarity with legal procedure might do their case harm and unnecessarily disclose material which might suggest to the complainant that he should pursue the matter in court. Under the regula-

tions a doctor could be brought before the committee on a charge of negligence, and it was not fair to expect him to defend himself without skilled aid.

In the course of discussion it was suggested that in police court cases the appearance of a solicitor with the defendant often resulted in heavy weather being made of the case, that a case would take on a fresh importance if there was legal representation, and that this magnification might be reflected in the penalty. The view was strongly held that the domestic type of jurisdiction was most suitable in these cases.

It was finally agreed that inasmuch as in about a year's time the committee would be reviewing procedure under the Act including that of the Medical Services Committee, it should then examine the position as further experience revealed it, being informed in the meantime of what took place on these committees, and on this understanding no move should be taken at present to alter the arrangement.

Constitution of the Committee

The committee devoted some time to considering its own constitution. It was agreed that in future it should consist of 33 members elected on a territorial basis by local medical committees, 6 elected by the Representative Body, 6 by the Annual Conference, 5 *ex officio* members, 3 or 4 nominated by other bodies with which it is desired to be in liaison, and up to 3 co-opted members if necessary to secure representation of a particular class, making a maximum possible total of 57 members.

A plan for the election of the 33 directly elected members on an area basis which gave as uniform an allocation of seats as possible to different parts of the country was approved.

It was agreed that the Annual Conference of Local Medical Committees, instead of being held in October, as was the old Panel Conference, should be held from next year onwards some time before the Annual Representative Meeting, probably in the month of June.

Many other matters remained on the agenda at the end of the day, and several were referred to the Executive. A report was made on the setting up of the Joint Committee (with the Central Consultants and Specialists Committee) to consider matters of interest to general-practitioner specialists. A difficulty appeared to arise with regard to a number of medical men and women engaged in hospital work who are strictly neither general practitioners nor specialists, such as permanent medical officers in the infectious diseases service, a proportion of tuberculosis officers, and some medical officers from local authority hospitals. Of a certain category, both whole- and part-time, it cannot be said that they are of full specialist status, and the fear is that the authorities may introduce specialists into this intermediate grade, making it a repository for specialists and for some who combine general practice with a specialty. It was stated that the Joint Committee, which was meeting this Ministry, was fully alive to this problem.

One outstanding matter before the committee is the Report of the Working Party on Midwives, on which the Association has been asked for its observations, via the General Medical Services, the Public Health, and the Consultants and Specialist Committees.

FELLOWSHIP FOR FREEDOM IN MEDICINE POLICY AND ACTION DECIDED

The second general meeting of the Fellowship for Freedom in Medicine was held at Caxton Hall, Westminster, on Feb. 1. Lord Horder presided over a gathering of about 500. He was supported on the platform by Dr. R. Hale-White, vice-chairman, Dr. E. C. Warner, honorary secretary, Mr. R. T. Payne, honorary treasurer, and other members of the executive.

Lord Horder said that the membership was 2,200—in London 580, and 1,620 in the provinces. The Fellowship had made a general appeal for members, but had been recruited by personal contacts, and the result was not unsatisfactory. It was seeking still informally, to set up local groups. A successful provincial meeting had been held at Cambridge, and others were projected.

It was obvious, he said, that since the inaugural meeting the general situation had deteriorated. The more need for it

llowship! Inquiry was often made, "What are you going to do?" The logical reply was, "Come in and help us to decide." If the Fellowship did all the things it was asked to by correspondents it would spend itself on petty, trivial things which led nowhere. Certain basic proposals would be acted before the present meeting.

The moral effect of the Fellowship's existence had been definitely good. It had had some effect on the B.M.A. As a member of the Council of that body his lips were sealed, but his colleagues who were also members agreed that there was something a little novel and very desirable about the business of the Council which was not noticeable before. Things were a little more definite. Instead of saying, "At an appropriate date," the Council now said, "By March 15"—or whatever a date might be. Some letters were received calling for resignation from the Association, but the directive from the inaugural meeting was that the Fellowship should work with her bodies as far as possible, and, after all, the Association is a big machine through which, up to now, the profession had voiced its views. There had also been moral effect outside the country. The Americans, who were becoming alarmed at the same thing happening to their profession, had shown much interest in the Fellowship's existence, as the London letter of the *Journal of the American Medical Association* testified. Some people said that moral effect did not count at the building up of the medical profession over 2,500 years, but that in solidarity and progress and continuity of tradition there was nothing to touch it, had been the result of moral effect. "It is silly to say that moral effect gets you nowhere. What else gets you anywhere?"

Constitution

Lord Horder went on to say that a number of letters had been received from members and potential members asking whether the Fellowship was going to be a trade union. At the last meeting he had said something, quite irresponsibly, about it. He was voicing his own views when, after asking whether they should be a trade union, he added, "God forbid!" He could not retract that, but letters had come in saying they could not get anywhere unless they were a trade union. That was for the meeting to decide. If it did not become a trade union the Fellowship would lose some members; if it did, it could lose a great many more. For his own part, if the Fellowship did seek trade union status, he could not continue in the chair. That would not be naughtiness or petulance on his part, but rank disappointment of such magnitude that he could just go out and grow his cabbages. It would mean a lost cause, and he was not very good at helping lost causes.

In any case it appeared that the medical profession, being neither masters nor workmen, could not effectively adopt trade unionism. But the question of trade union status for the Fellowship had been considered in relation to the constitution, and he would put it to the meeting.

The legal adviser (Mr. Moir, of Messrs. Withers and Company) explained the legal position with regard to trade union status. If one speaker argued that as nearly all of them were in the H.S. they were surely "one body against the Government" and therefore entitled to trade union privileges. But the feeling of the meeting was overwhelmingly against such a policy. In reply to one or two who expressed themselves still dissatisfied, Lord Horder said that the matter was not closed. Things were changing very rapidly, and even a meeting of the Fellowship might take a different view in six months' time. He was not prejudging the future, but for the present the matter must be regarded as closed.

The meeting then discussed a memorandum of association in which the objects of the Fellowship were set out under headings (a) to (r). The first three were as follows:

- (a) To insist upon the preservation of the highest standards of medical practice.
 - (b) To protect the public and the medical profession from State monopoly in medicine.
 - (c) To preserve the ethical and professional freedom of the individual doctor in the service of his patients and to maintain the status of the general practitioner, including his financial security.
- Other objects were to oppose encroachments of the State, to define the limits of State medicine, and to support and protect the character, status, and interest of the medical profession generally.

Many suggestions were made from the meeting for improvements in wording, but the only one which was adopted was the substitution of "medical practitioner" for "general practitioner" in object (c).

The memorandum and articles were approved.

Repeal or Drastic Amendment

The first question of policy and action which was brought forward was whether the Fellowship should press for the repeal or, alternatively, the drastic amendment of the Act. Lord Horder said that they were agreed that it was a bad Act, but it was on the statute book, and to some of its sections there was nothing like the same dissent as to others. The question came down to what was practicable at this stage. If repeal were made the main objective of the Fellowship all its other activities would be small in comparison, and what would be the hope of success? (A voice, "None.") But they had had letters urging strongly that they should work for repeal as against drastic amendment—"amendment possibly so drastic that in effect when we have finished the job it will be emasculated and not the same Act, though it may remain on the statute book, as many dead Acts do."

Some speakers urged that they should go all out for repeal. Dr. C. E. Taylor (Purley) asked whether the Fellowship was prepared to accept "the nationalization of the family doctor." Dr. E. D. Broster (Wirksworth) thought that the Act should be attacked on general public grounds, saying that it had produced a sickness-minded population. It was an encouragement to every work-shy malingerer in the community.

The meeting decided by a very large majority to press for drastic amendment rather than repeal, and then turned to consider in what respects revision of the structure of the Act should be sought.

Minister's Powers of Appointment

Mr. Norman Lake urged that they should seek limitation of the Minister's powers of appointment, as, for example, to the Central Health Services Council and other administrative bodies. He cited Sect. 66 of the Act, under which

"Regulations may make provision with respect to the qualifications, remuneration, and conditions of service of any officers employed by any body constituted under this Act. . . ."

Why had the Minister been given these enormous powers? Mr. Bevan had stated that he was responsible to Parliament and must have sufficient control to ensure that the provisions were carried out. That sounded reasonable enough, but the real answer was to be found elsewhere.

Here Mr. Lake quoted an article written by the present Chancellor of the Exchequer some time before the present Government came into power. It was entitled, "Can Socialism Come by Constitutional Means?" and in it Sir Stafford Cripps suggested certain methods which must be adopted, as, for instance, that general planning and enabling Acts should be passed by Parliament and once passed should not be discussed by Parliament at all, but that the Acts should deal only with general provisions and the details should be decided by regulations. Sir Stafford Cripps also proposed that the right of appeal to the courts against a ministerial order should be abolished, and that the power of local bodies should be nullified by placing them under State-appointed regional councils, such councils to be filled by staunch party members who would see that ministerial orders were carried out efficiently. The close resemblance of the present Health Act to this forecast, said Mr. Lake, would be appreciated. The implication was complete party political control, and the doctors must be sacrificed and become mere pawns in the game.

The effect of Mr. Lake's speech was such that the meeting agreed without discussion that the Fellowship should strive for the limitation of the Minister's powers of appointment.

Teaching Institutions and Control

Mr. Reginald T. Payne proposed that the Fellowship should strive also for the exemption of undergraduate and postgraduate teaching institutions from the control of the Minister. He declared himself a critic of planning. When he saw these vast schemes of planning all his scepticism rose to the surface because so many of the schemes created more problems than they solved. His opinion of the Act was that it was the worst

that had been placed on the statute book affecting the medical profession. It "stank of dictatorship." The battle was one of doctors versus politicians. "When the Government gets legislative diarrhoea the body politic is weakened, and astringent action is called for. We are hoping to furnish that astringent action."

A good health service, Mr. Payne continued, could be maintained only if there was a healthy independent profession of medicine outside the State Service. Under the present scheme all hospital buildings belonged to the State. All medical teaching was carried on in such institutions. No comparable state of affairs existed in any other faculty. He mentioned the Central Health Services Council, with its 35 nominees of the Minister, against whom their own professional and educational leaders were in a small minority. The chairman of the council, a layman, had said recently that for too long the needs of the people had been subservient to the needs of medical training. What about the Royal Colleges, whose presidents—unhappy men!—were on that central council? The Colleges should represent the highest professional, educational, and ethical standards in the medical community. So far as he knew, none of the three presidents had joined the Fellowship. Medical education had been handed over to the control of the politician—a most dangerous and disastrous thing. If it continued, they might have to consider the establishment of independent Colleges outside.

This point also—the exemption of teaching institutions from the control of the Minister—was agreed to as a line of policy.

Ownership of Goodwill

Dr. A. C. E. Breach moved that the Fellowship should strive for the restoration of the ownership of goodwill in practices. It had often been said that the medical profession was the spearhead in the fight for the survival of the middle classes. The deprivation of goodwill struck at the very core of their freedom. The right to goodwill belonged to everybody, from the small shopkeeper up to the great stores, from the market gardener to the farmer of a thousand acres. It covered nearly all the professions, all the crafts. By giving faithful, attentive, honest service the giver had built up his goodwill. It had been said by the Government that what the profession was really fighting for was the right to sell the bodies of their patients. That was malicious nonsense. It was the right to pass on an introduction, and it remained for the patients to decide whether they liked the newcomer or not. It was true enough that the fight over this should have been waged last year, and they could never quite forgive their leaders nor themselves "who ran away from potential victory and succumbed to a simple threat of blackmail." They were told also that any fight on this point would be very strenuous, and that they would have no political support whatever. But it was their fight, and in waging it they were fighting the battle for the middle and professional classes everywhere.

The discussion on this point evoked some dissent. One member said that it was nonsense to talk about "selling patients," but what right had the doctor to take a capital sum for the services which he had rendered in the past and for which he had already been paid? Moreover, a man might sell his practice, not to the best person to carry on his work, but to the highest bidder. The profession was against canvassing, but what more effective method of canvassing could there be than to recommend a successor simply because a capital sum had been paid for his introduction?

Lord Horder said that the letters received on this point had rather stressed the impracticability of restoring ownership of goodwill, but that might be a defeatist attitude. There had been no enthusiastic mail in the other direction. Did the meeting wish this to be made one of the planks in the platform?

There were cries of "Yes," and the affirmatives had it by a large majority.

Other Points of Policy

Dr. Goodwill (Attleborough) urged the insertion of a clause permitting grants in aid ("contracting out") towards the cost of medical services in private wards of hospitals or performed for private patients elsewhere. Dr. Beare (Dorking) said that the profession had accepted the 100% inclusion only with the proviso that any members of the community, whatever their

income, should be entitled to obtain medical services, in part or whole, privately.

This point was agreed to, and on a related matter the chairman said that the right of a private patient to have his prescription dispensed under the N.H.S. would shortly come before a county court, where a patient was suing the Minister.

Dr. R. Hale-White briefly touched on the question of remuneration. The method favoured by the profession was an increase in the capitation fee for the first thousand on the list and a large increase in the present hopelessly inadequate betterment factor. When the decision was made he hoped it would not be subject to bargaining, but that the profession would state what it intended to have and considered fair, and would brook no other figure.

The final point concerned relations with other bodies. Lord Horder said that at the inaugural meeting he had declared that the Fellowship was no breakaway organization.

"If and when we are confident that the B.M.A., whether by reorganization or otherwise, and/or the Royal Colleges accept and carry out the obligations to the profession and the public for which we stand we can dissolve, but that time is not yet."

If they did not take the view that they were in definite and positive opposition to the B.M.A. they would lose perhaps 100 members; if they did declare that opposition they would lose perhaps four times that number. He was not suggesting that numbers should settle the matter; they were out for quality, not quantity.

"Is it your view, as it was in November, that at this juncture we do not oppose by any active steps the Association or any other body?" ("Agreed.") "Critical? Oh, yes. Ginger? Yes." (A voice: "May we say that we are out to capture the Association, peripheral and central?") "Well, I would not dissent from it as a long, long view, but it is not necessary. Reforms take place in bodies as old and adamant as the B.M.A. It depends who is there to help. Then our policy remains as it was enunciated at the first meeting."

Those present subscribed to this view by general applause, and the meeting terminated.

BASIC SALARY APPEAL

On July 5, 1948, two doctors who had previously been assistants to two partners practising in a northern town became third and fourth partners in the practice and were placed on the executive council's medical list. These two doctors applied for the basic salary. The first partner had 2,400 patients on his list and the second, who was doing part-time specialist work, had about 760. The third and fourth partners had 740 and 620 respectively—a total of about 4,500. The second partner resigned from the practice three months after the appointed day, and the executive council gave permission for his list to be divided equally among the three remaining partners, who then shared the receipts of the partnership equally.

Appealing jointly against the executive council's decision not to grant their application for basic salaries, the two junior partners contended that the annual income of the partnership had been reduced from £8,000 to less than £3,500. They considered that the total list of 4,500 was a small one for the partnership and that, unless the £300 were granted to them both, they would suffer hardship for the first few years while building up the practice. They stated that the receipts of the partnership still showed a marked decrease and the number of patients on the list provided an inadequate income. The executive council and the L.M.C. said that they had felt the applications should be considered in the light of the partnership. The two former assistants and the other partner shared equally the receipts of the practice; 4,500 patients were considered sufficient to provide an adequate income for the three doctors without undue hardship.

In deciding not to allow the appeals the Minister took account of the following facts: (1) The doctors could not be regarded as starting a new practice because they took over shares in the partnership. (2) They were suffering no loss of income due to the National Health Service, for prior to July 5 they were assistants. (3) As this was an equal partnership, the granting of the basic salaries would benefit the partnership as a whole and not these two doctors particularly, yet the capitation fee would be reduced in respect of their two lists only.

CONFERENCE OF REPRESENTATIVES OF SCOTTISH LOCAL MEDICAL COMMITTEES

An all-day conference of representatives of Scottish Local Medical Committees was held at B.M.A. House, Edinburgh, on Thursday, Feb. 10, 1949. Members of the General Medical Services Subcommittee (Scotland), Dr. Wand, Chairman of the General Medical Services Committee, and Dr. Stevenson, Deputy Secretary, also attended. Dr. William Knox, Glasgow, presided, and in his opening remarks explained that such opinions as the Conference might express would not be binding on anyone, but that they could and would be referred to the General Medical Services Subcommittee (Scotland). It would be useful in any case to know the consensus of Scottish opinion on a number of the matters on the agenda.

Eight motions on the agenda touched on the question of the capitation fee—which the Conference, without dissent, considered "grossly inadequate."

The principal debate on the subject centred round a motion by Perth and Kinross that payment should be by a fixed capitation fee; paid without deduction, with separate fees fixed for temporary residents, emergencies, anaesthetics, and other contingencies, plus a sliding mileage scale with a fixed unit value, plus an inducement payment where necessary.

Dr. McDonagh, who moved the motion, said the position at the moment was that they looked forward to adequate remuneration at the end of the quarter, but all they found was that the capitation fee they were promised was cut up and diverted into various channels. The present system produced the anomaly of practitioners all over the country getting different rates of remuneration for the same work. What the profession wanted to know was what they would get for a particular job.

Dr. Wand said that what they had to see was that the total sum received by the doctors in this country for the job done was the right one and that it was properly distributed. He described in considerable detail proposals likely to be made to the Central Conference on March 3.

The Perthshire motion was defeated by a large majority.

The Special Inducement Fund

During a debate on four resolutions on fixed annual payments and inducement payments Dr. Wand urged members of the profession to avail themselves of the Special Inducement Fund. Some men, he said, felt it was like making application for public assistance relief and that there was a means test, but he thought it was right and proper that those who administered the Fund should assess the needs of the applicant, which could be done only by assessing income. The number of applications under the Fund had been so small that nothing like a fraction of the Fund available had been expended. "I urge that anyone who knows of a case in which there is hardship should see that application is made to this Fund."

The Scottish Secretary, Dr. E. R. C. Walker, explained that the Department of Health's view on the Inducement Fund was that, as the name implied, it was intended to deal with types of area rather than just any case of hardship, as the Ministry now seemed to suggest. On his suggestion the Conference agreed that the matter should be referred to the General Medical Services Subcommittee (Scotland) to take up with the Department.

Dr. Wand's appeal arose on a motion by Aberdeen that the scope of the Inducement Fund should be widened and that it should be renamed in order that consideration might be given to applications for payment from the Fund in cases of special hardship.

Dr. Kellie Brooke on behalf of Kirkcudbright and Wigtown Local Medical Committee suggested that the following formula should apply to the whole of Scotland: Capitation rate multiplied by the number of patients, plus a fixed annual payment (where applicable), plus annual mileage payment, plus inducement payment, equals £1,500. His committee's difficulty was in knowing when an inducement payment was necessary and up to what level.

After some discussion, during which the figure of £900 net was mentioned by Dr. Wilkie Millar as being under considera-

tion by the Medical Practices Committee, the motion was withdrawn, the Conference approving the general principle involved.

Of six motions on the agenda on mileage payments, four were withdrawn. The first of the two remaining—that by Roxburgh, Berwick, and Selkirk, that mileage should be paid from a separate fund and not deducted from the Practitioners' Fund—was defeated on a vote. The other—by Inverness—that mileage for maternity services should be separated from ordinary mileage and should be paid on a running basis and not on a case basis, was referred to the Maternity Services Subcommittee.

X-ray and Diagnostic Facilities

Dr. Robertson, Edinburgh, spoke at length in submitting a motion that general practitioners should have direct access to x-ray facilities without the necessity of prior reference to physicians or surgeons at an out-patient department. His motion also asked the Conference to recommend that the possibility of employing radiologists and their equipment for the National Health Service should be favourably considered. The motion was on the agenda, he said, because of the action of a regional hospital board in the West of Scotland in rejecting such a proposal. If such facilities were available they would greatly enhance the work of the general practitioner. At the same time, however, it was realized that if such a proposal were carried it would embarrass radiologists, and for that reason they included the recommendation in the last part of the motion.

The resolution was accepted without a division.

There were two motions on the question of the provision of diagnostic facilities. The first, by Lanarkshire, proposed that diagnostic centres should be set up in all areas. Commending the motion to the conference, Dr. McArthur said it was hoped that such places would provide a centre where laboratory diagnostic procedures could be carried out for the local practitioners by qualified technicians. Others felt that radiological equipment should be available and that there should be an attendance of consultants at certain periods. The establishment of such centres would help to relieve the general practitioner of the extra work he had to do, especially in his surgery. The other motion, also by Lanarkshire, was a development of the first, and proposed that where a health centre was established all practitioners in the area, whether practising from a centre or not, should have available all consultant and diagnostic facilities provided therein.

It was pointed out that meantime the ruling of the Department of Health was that only the patients of those doctors practising from the health centre could be treated at the centre, the others being deprived of such facilities.

Both resolutions were unanimously accepted.

Expenses for Attending Meetings

There were five motions on the question of expenses in connexion with attendance at meetings of local medical committees.

In the course of the general discussion Dr. Wand intimated that the matter was to be considered at a meeting of the General Medical Services Committee the following week.

On behalf of the Highlands and Islands it was pointed out that many practitioners had to travel by sea or air to the mainland and were absent from their homes for two nights. It was claimed that in such cases a subsistence payment ought to be made in addition to travelling expenses.

Dr. Walker pointed out that Sir George Henderson at a meeting with the General Practices Subcommittee of the Scottish Negotiating Committee had undertaken to consider the possibility of the adoption of the Subcommittee's suggestion that travelling and subsistence allowance should be paid in the Highlands and Islands executive council areas.

Dr. Wand said he would look into the possibility that arrangements might be made for the payment of travelling expenses from the Central Fund, but he was not hopeful in regard to payment for subsistence.

The Conference remitted to the General Medical Services Committee a motion by Dumbarton on the deductions made in respect of assistants in assessing a principal's income for superannuation purposes.

By a majority the conference decided that the committee representing general practitioners under the National Health Service in Scotland in discussion with the Department of

Health for Scotland did not require more autonomy than had the similar body under the old National Health Insurance Scheme.

A large majority carried a motion moved by Edinburgh that the General Medical Services Committee (Scotland) should be formed by the election of representatives of each of the 25 local medical committees in Scotland. Other proposals in the motion—that the number from each local medical committee need not necessarily be on a population basis; that there should be *ex officio* members from the Central (National) Committee; and that the Scottish representation on the Central Committee should be by election from the members of the Scottish General Medical Services—were remitted to a subcommittee for further consideration.

The Conference referred to the General Medical Services Subcommittee (Scotland) a motion on the question of the preparation of a model scheme for the election of local medical committees in Scotland.

Other motions directly associated with the scheme which were discussed included a proposed free supply of medicines to private patients; certificates of incapacity required by employers; the provision of locums; telephone charges in rural practice; filling of vacancies in general practice; and the appointment of a committee at Scottish Headquarters to deal with the problems of general practitioners in Scottish hospitals.

Lastly, the Conference gave their unanimous support to a motion calling attention to "the very unsatisfactory state of the tuberculosis service throughout the country and particularly to the fact that open and infectious cases were kept at home in overcrowded houses."

Dr. Douglas Robertson urged upon the Conference the importance of the subject. Responsibility for the present position, he said, must lie at the door of the community, with the Minister of Health, and to some extent also upon the medical profession. "It is up to us to keep hammering away at the stone wall of complacency."

The Conference closed with votes of thanks proposed by Dr. Ian Grant, Glasgow.

PSYCHOLOGICAL MEDICINE GROUP

A meeting of the Psychological Medicine Group will be held at B.M.A. House on Monday, March 7, at 11.30 a.m. to receive a report from the Group Committee and to discuss matters of interest to members of the specialty. The main theme of the discussions will centre round the Hospital Index Cards 1 and 2 which have been introduced into mental hospitals for statistical purposes. Dr. C. P. Blacker, F.R.C.P., London, will address the conference in the morning on the value of the statistics to research in genetics, and in the afternoon Professor T. Ferguson Rodger, of Glasgow, will speak on the value of diagnosis in clinical records in mental hospitals. The Group Committee hopes that as many members as possible will attend, and extends a cordial invitation to all non-members of the Group who may be interested.

HEARD AT HEADQUARTERS

The First Thousand

The proposers of the plan to have a larger capitation fee for the first thousand on the list showed a certain anxiety lest the proposal be misunderstood. It scarcely seems possible for the most casual person to suppose that it benefits only the practitioners with small lists. Obviously it benefits all practitioners. If the augmented rate for the first thousand is 30s. (the figure is taken only as an example and for ease in calculation), it would mean an increase of £629 in the remuneration of the practitioner with only 1,000, as compared with the present rate of 17s. 6d., but it would also mean an increase of £629 for the practitioner with a list of 2,000, or 3,000, or 4,000. It is not therefore a scheme for having two classes of practitioners, one paid at a lower and the other at a higher rate. Nor does it mean two classes of Service patients, for the question whether a patient is within the first thousand or within a

subsequent thousand, or is on a short list or a long list, will make no difference than it does at present.

Echoes from Yesterday

In her posthumous book *Our Partnership*, recently published, the late Mrs. Sidney Webb makes some unkind references to the British Medical Association of forty years ago, at the time when she and her husband were campaigning for the abolition of the Poor Law. She speaks of the Association as representing, or being, "inferior medical practitioners fearing the encroachment of preventive medicine on physick mongering." Later, at the time of the Insurance Acts controversy, she speaks of the B.M.A. as having only one idea, to protect the interests of the worst type of medical man by a futile insistence on free choice of doctor. Mrs. Webb considered free choice an "obvious absurdity," as absurd as free choice of teachers by school-children or by parents—indeed, more absurd than free choice by parents would be. With her brilliant mind, Beatrice Webb combined sharp judgments on men and things, and the B.M.A. is in good company under her denunciations. For example, she refers to Mr. Churchill as "egotistical, bumptious, shallow-minded, and reactionary." Some prominent B.M.A. figures come into her narrative, including "the unfriendly Tory president of the B.M.A.," the allusion being to Dr. Macdonald, of Taunton, who was not President but Chairman of Council. Dr. Smith Whitaker, the B.M.A. secretary, also comes in. She says that he was not unfavourable to her plan for transferring Poor Law medical relief to public health authorities. She asked him, "Is the B.M.A. going to dominate the new service or is it not? If it throws itself at once on the side of the new regime then it will dominate it; if it opposes this development, the new scheme will organize itself as a rival." "That is what I tell them," said Smith Whitaker. Much traffic has rolled down Whitehall since those battles of long ago.

Dear Doctor

A doctor has received the following letter from a patient: "Dear Doctor X,—Two years ago you gave me some tablets to get my weight down, which I did (18 lb.). Now I find I keep rapidly gaining again—nearly 13 st. As I am only 30 years of age surely this is far too much. I put on about 2 lb. per week. May I have some more tablets, and I will stick to a diet again? I was wondering if it was possible to have some of the new stuff they use for jockeys and fighters that gets their weight down without a lot of diet. I would be quite willing to pay for it as a private patient, as I don't suppose it comes under the scheme. Perhaps you would let me know. I've only put on all this weight since Y. was born in 1944." This letter is in a rather different vein from others. There seems to be some doubt about what the N.H.S. can do.

In Favour

A correspondent tells us that having been placed on a short list of candidates for a vacancy on an executive council list he was asked by the chairman of the interviewing committee: "Are you in favour of the National Health Service, and how do you propose to carry out its projects in the area of the practice in the event of your appointment?" We do not know what his answer was; expediency would seem to have demanded "Yes" to the first part, for the chairman is said to be a prominent Socialist. In any case it is wholly undesirable that a candidate for a vacancy should be subjected to what can be interpreted as a political test. The chairman then asked: "As you are married and have children, how do you propose to arrange for the education of your family?" It is difficult to see what bearing this impertinent question can have on a doctor's fitness to practise in any area, and again we are left wondering—as the candidate was—whether political considerations prompted it. Is the approved answer, "At a State school"? What makes the matter worse is that both these questions were read out from a list, so presumably they had been carefully considered and represented a defined policy.

Contact Men?

We have heard a lot about contact men recently—those obscure catalysts facilitating transactions between the Govern-

agent and the public—and it seems that some people imagine their doctors to be in that category. Gone are the days—for them—of falling ill, seeing a doctor, being cheered by his keen interest in an important case, cured by his incomprehensible prescription. "Positive health" is their aim, and a line to their doctor will bring the resources of the State to their door. A doctor sends us a note that he received the other day: "Will you give Harold M. 4 week certificate put date Sat. 22, 1949, also will you give him a note for extra coal and a note for hirts vests and pants. . . ." Another doctor sends us the following: "To Doctor X. Please may we have our tonics renewed 'One for Albert' (Cod Liver Oil and Malt and iron tonic), a tonic for Gran (80) to help her sleep and keep her good-tempered, and may I have some tonic capsules for James: he's 15½ and taking his school cert, something to keep him fit and energetic, and lastly may I have some capsules or something to keep the family fit and if I may have something to help me sleep (middle age you know) and thank you for all you've done in the past and all you'll be doing in the future."

Questions Answered

Trainee Assistant

Q.—*I applied to the local executive council for the employment of a trainee assistant. The assistant started on Dec. 1, 1948. Will his remuneration be paid from that date, the council being aware that the assistant started to train as from Dec. 1?*

A.—The grant is payable from the date on which the assistant takes up the appointment, or the date on which approval of the training grant is notified, if the appointment has been made beforehand.

Prescribing Spencer's Support

Q.—*Can Spencer's support for left inguinal hernia be obtained on Form E.C.10?*

A.—The Ministry's view is that this is not a truss but a type of belt, and therefore it cannot be prescribed on Form E.C.10 as the Third Schedule stands.

Basic Salary and Partnership

Q.—*Just before July 5, 1948, I purchased a half-share in a partnership in general practice. Both my partner and I applied for the fixed annual payment of £300 per annum. My partner's application was granted; mine was refused. Over 90% of the patients in the practice are on my partner's panel. In computing our quarterly cheque our local executive council deducted one-seventh of the number on my partner's panel before paying the capitation fee. Should they not have deducted the one-seventh from half the number of patients on our combined panel, as by the terms of our partnership agreement half the patients are really mine and the Minister undertook that partnership agreements would not be interfered with?*

A.—Normally, practitioners in partnership pool all their earnings and draw out from a common account in proportion to the share of the practice they hold. Unless some other arrangement was mutually agreed by the partners concerned, the fixed annual payment of £300 and the automatic adjustment of the capitation fee would be likewise pooled. Thus the executive council is correct in deducting one-seventh from the capitation fee in respect of the number of patients on your partner's list.

Examination of Traveller

Q.—*A well-to-do patient came to see me last week with a request that I should examine her, since she had to be certified as fit (especially in regard to tuberculosis) before being accepted to join a party at a Swiss hostel. I did not request a fee for this service, but it has since occurred to me that the scope of the service rendered was outside the National Health contract. Is this so or not?*

A.—You are required by your terms of service to render all proper and necessary treatment to one of your public patients. You are therefore debarred from charging the patient for the medical examination. But if the patient requires a medical

report for the purpose of joining a party at a Swiss hostel you can charge an appropriate fee, since such a report is not included among the list of medical certificates which are required to be given free of charge.

Circumcision

Q.—*Are circumcisions performed on babies considered to be under the terms of service of medical practitioners, to whom it is open to refer the case to hospital for operation, or can I charge a fee? The point arose in connexion with a baby a week old who had a tight foreskin, and I considered it necessary to circumcise the baby, though I was not given a medical aid form for that because I had been called to attend the mother. I claimed for attending the baby in addition on form M.20, but this was disallowed on the aforementioned grounds.*

A.—The view of the Ministry is that the remuneration payable to general practitioners must be inclusive of all treatment carried out which does not demand special qualifications or experience. It recognizes that there are various items of treatment which, while not regarded as being an obligation upon all practitioners under their terms of service, some practitioners will wish to carry out, but, having regard to paragraph 10 (i) of the terms of service, no extra remuneration will be payable where they do. Circumcision, infantile and adult, is held by the Ministry to be covered by the above ruling. If the patient, however, is not on the doctor's list or the list of his partner or assistant a fee may be charged in the ordinary way.

Claim for Compensation

Q.—*I have to pay interest and capital on a large sum of money borrowed to purchase my practice in 1946. I understand that payments on account of compensation are now being made. I should be grateful if you would inform me of the steps necessary to claim a payment on account of compensation due to hardship.*

A.—Under the Medical Practices Compensation Regulations, 1948, a practitioner who claims to suffer hardship by reason of the non-payment before the date of his retirement from practice or death of compensation to which he is entitled under these regulations may at any time submit to the Minister a request for immediate payment of the whole or any specified part of the compensation to which he is entitled or, if the amount of compensation payable to him has not been ascertained, for an advance payment on account thereof. Claims, giving full details of the grounds on which they are made, supported by such written evidence as is considered necessary, should be addressed to the Secretary, Department A.G.D. 3, Ministry of Health, Whitehall, London, S.W.1.

Anaesthetist's Fee at Confinement

Q.—*Is any additional fee payable for the services of a second doctor when required to give an anaesthetic at a confinement? What form should be used?*

A.—If the maternity service is being provided under the arrangements of the Act, it is the responsibility of the first practitioner to notify the local executive council on Form E.C.24 or 24A that he has called in a second practitioner to give an anaesthetic, and the executive council would then submit a claim to the local medical committee, which would decide the appropriate fee for the service. If, however, the case was a midwife's emergency, the fee for giving the anaesthetic is £1 15s. and should be claimed by the first practitioner on the official form of report submitted to the medical officer of health.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

Correspondence

Payment of Clinical Teachers

SIR,—Would the problem of payment of clinical teachers not be best solved by a frank recognition of the fact that the appellation "whole-time teacher" is a misnomer? All such teachers are obliged to do clinical work, and their clinical responsibilities are identical with those of their colleagues on hospital staffs. Previously it was necessary to practise privately to gain an income from clinical work, and in consequence the universities invented the myth of the whole-time clinical teacher. The necessity for prolonging this pretence no longer exists. Why not say so?

A part-time salary as a teacher and a part-time salary under contract with a board of governors, with suitable restrictive clauses on both sides, would clear the air from every point of view. Clinical teachers of all kinds would then know exactly where they stood, the hospitals would be on proper terms with their staffs, and the universities would have lost nothing. Indeed, their anxieties as to the future of their salary scales could only be eased by such an arrangement.—I am, etc.,

Liverpool

CHARLES A. WELLS.

Loading the Capitation Fee

SIR,—Here we are faced with the problem of enabling the man with a small list—say 1,000 upwards—to remain solvent without diminishing the emoluments of the man with the big list, and at the same time keeping within the recommendations of the Spens Report. In order to do so it is necessary to consider the approximate expenses or outgoings of a sample of general practitioners taken throughout the country, which gives the following figures:

	£
Allowed for income tax purposes	757
Disallowable expenses	270
Income tax, housekeeping, clothing, etc.	862
Total ..	1,889

At the present rate of remuneration the doctor with 1,000 patients on his list would receive £986 if granted the basic salary, or £800 without. How can this class of doctor become solvent? There are several ways:

By loading the capitation fee to £2 per head for the first thousand. Is this possible? After much juggling, with the aid of my accountants we found it was *not*, because if the first thousand had a capitation fee of £2 per head—i.e., big enough to cover all expenses—it would be impossible to preserve equity with larger lists and still keep within the Spens Report. The following computation is therefore suggested:

No of Patients	Capitation Fee	Total	Balance Credit or Debit
1st 1,000	£1 10s	£1,500	Will require a basic salary or expenses allowance to meet his liabilities
2nd 500	£1 5s	£625	Just about covers his expenses
3rd 500	£1	£500	Has a balance credit of about £300
4th 500	15s	£375	Has a balance credit of about £500
5th 500	15s	£375	Balance credit increased but income tax much heavier
6th 500	10s	£250	Big lists require to be discouraged in future
7th 500	10s	£250	

List of 4,000 produces which is within £700 of present scale.

After many hours working on the problem it was decided that it is impossible in equity to others to make the man with 1,000 patients solvent except by basic salary or expenses allowance. The idea, therefore, was abandoned with regret.

What are the advantages of this method of meeting the situation? It would raise the average rate of payment for those men who on change-over from private to State practice, have now small lists, or whose geographical position renders it impossible to collect large ones, and make them solvent without interfering with the remuneration of the larger lists. It would meet the difficulty that the ratio of expenses to receipts in the smaller practices is much higher, and would in all except

the 1,000-and-under lists enable the basic salary to be abolished except for new entrants and the aged, and also the Inducement Fund except in special cases. It would greatly help the young man starting in practice, who otherwise would find it difficult to make ends meet. It would tend to discourage the swollen lists and help in time to spread patients more evenly.

Disadvantages: It would tend towards laziness in some practitioners; but there are black sheep in every flock, and I am sure the percentage would be very small compared with the overall benefit obtained. The reason for the small list would also soon be known to the executive council, which would take what action it considered necessary where abuses were known to exist.

Alternatively by expenses allowance.—An expenses allowance sufficient to cover the minimum basic professional charges before a man can go into practice at all might be granted, in which case the capitation fee would be by way of "remuneration for professional services," the doctor's total emoluments being built up in this way with the addition of mileage, etc., where applicable.

Advantages: The young man just starting in practice would have enough to make ends meet until he attracted patients to himself. The elderly practitioner would be able to ease off and still pay his way.

Finally, there is the method suggested by me, published in the *Lancet* of March 22, 1947, which as a long-term view has much to recommend it but cannot be dilated on here.—I am, etc.,

Worthing, Sussex.

HAROLD LEESON.

Graduated Capitation Fee

SIR,—When in May last the profession astonished the world in general and Mr. Bevan in particular by its precipitate surrender it left unsettled, and in large measure undiscussed, nearly all the really important details of the Service to which it committed itself. One of these important details, itself closely linked with the question of remuneration, is the faulty distribution of general practitioners in relation to the population of the country.

Before the Service started it was possible for a doctor to earn a very satisfactory living with 1,000 patients if these were private patients of substantial means accustomed to look to their doctor for individual care and consideration and to pay him accordingly. And such a doctor might well put in just as long hours and devote just as much skill to his work as his colleague at the other extreme who worked a vast panel and contract practice in an industrial area. Each doctor had selected the type of practice he preferred, and neither would have felt at home in the other's shoes. All this is arbitrarily changed by the advent of the N.H.S., and while the doctor in the industrial practice is working harder than ever and is earning substantially more the man with the small list practising in the "over-doctored area" is facing stark ruin. From the public point of view the position is thoroughly bad, for it means that skilled man-power is to an extent being wasted.

All this was abundantly obvious years ago, yet nothing was done about it; and in May our leaders advised us—and we accepted the advice—to enter the Service trusting to the well-known benevolence of our new autocrat to smooth away the difficulties. This is one of the many really bad features of the N.H.S. Act, and one of which we must demand amendment as a matter of urgency. It is no solution of the problem to say, as some of the "planners" do, that it will be resolved in time by supply and demand reinforced by the Special Inducement Fund. Such a process would take 10 or 20 years, and in the meantime what is to happen to the doctor with the small list? Is he to be forced out of his home and the practice in which he has worked for years by economic pressure and to become a suppliant to this committee and that for permission to practise his profession in some district where doctors are scarce?

Under existing conditions the financial inducement is entirely towards numbers without regard to quality of work. The best income is to be earned by the doctor who is prepared to act as a sorting-room clerk, passing on his patients to hospital without even troubling to make a diagnosis. A few friendly words of reassurance, a suitable batch of certificates, a brief introductory note, and the responsibility is shifted in a very

few minutes without loss of goodwill. By this means very large numbers of patients can be dealt with. But are we really content to prostitute our skill and our training in this way? Arbitrary methods of control by way of direction, whether positive or negative, are highly obnoxious in a freedom-loving community, and must be resisted in the interests of the nation no less than of our own profession.

The basic salary is, of course, a half-hearted attempt to meet the difficulty of the doctor with a small list. It is objectionable in that it certainly constitutes a step towards State-salaried service and that it is wide open to abuses of various kinds. Mileage grants, even with the latest increases, are wholly inadequate to meet the needs of the practitioners in a sparsely populated area in that no account is taken of the time they are compelled to spend in transit. The Special Inducement Fund if fully applied would do little more than scratch the surface of the problem. It has, moreover, been badly publicized and to most doctors wears an unpleasant odour of charity.

What then is the solution of the problem of securing that in a reasonably short time doctors will be so distributed through the country that the public is adequately looked after and that each practitioner has a sufficient income without the necessity of taking on so many patients that he has no time to devote his skill to any of them? The arbitrary lowering of the ceiling from 4,000 to 3,000 or 2,500, coupled with a very substantial raising of the capitation fee, would no doubt solve one aspect of the problem, but it would leave large numbers of patients in crowded industrial areas without a doctor. It is, moreover, objectionable in that it constitutes yet another arbitrary interference with freedom.

There remains the method of the graduated or tapering capitation fee. For example:

- A capitation fee of 35s. for the 1st thousand patients
- A capitation fee of 30s. for the 2nd thousand patients
- A capitation fee of 25s. for the 3rd thousand patients
- A capitation fee of 12s. 6d. beyond 3,000 patients

This method has much to commend it in that it provides for all types of men and women practising in the Service. Those who prefer to limit their lists to 2,000 patients in order to deal with them fully and intimately are able to earn an adequate income, while those who delight in a large practice are rewarded for their popularity and their extra labours, but on a diminishing scale as the numbers on their list approach the limit of efficient work. Above all, the individual is free to make his own choice as to the type of practice he will have. He is free from the coercion and the arbitrary control which characterize the other methods.—I am, etc.,

Orpington, Kent.

A. C. E. BREACH.

SIR,—I would like to add my support to the plea of Dr. C. W. Warner (*Supplement*, Feb. 5, p. 59) for a careful consideration of the suggestion of the Secretary that a graduated capitation fee might go far to solve our present difficulties (*Supplement*, Jan. 15, p. 21). Dr. Warner, following Dr. Reginald Deane's review (Jan. 1, p. 5) of the financial rewards and responsibilities of general practice, makes the obvious point that it is quality as well as quantity that should be rewarded, but it is one of those obvious points that are so easily forgotten by the planners. Now, real quality in general practice cannot be assessed in figures; it is one of the imponderables, depending on personality as well as training and the fitness of the man for his job. Financial rewards will not create it. All we ask, therefore, is that the lack of them should not actively discourage it. That, however, is precisely what the uniform capitation fee, with financial rewards only for big lists, and no extras, is bound to do. There are some, especially in the prime of life, who may be able to "deal" with 3,000 patients, but should they be rewarded beyond those whose method it is to give more time, offer their patients the results, perhaps, of a riper experience, and perform services ranging from simple psychological explanations to items of minor surgery, the necessary skill for which they have acquired through the years? I suggest they should not.

Now, a graduated capitation fee, providing a reasonable income for the man who, by necessity or choice, keeps his list at about 1,500, and offers considerably less reward *per capita* if he increases it above that figure, will favour the type of practice that we can most approve, and the type that a con-

siderable proportion of the population have been used to in the past and have paid for at fees varying from 5s. to 10s. 6d. per visit, in fact the solid body of middle-class private practice by means of which we have for years subsidized, and made possible, our panel practice. These middle-class patients still expect—and in my submission have a right to expect—similar services under the State scheme. It is a fallacy of egalitarianism to suppose that the business man or university professor can be given the medical services he needs as quickly as the labourer. In the former case the whole mode of approach must be different to obtain and retain confidence, explanations of the illness are demanded more often, and alternatives of treatment and disposal more fully discussed, so that the doctor practising among the higher strata of society must of necessity spend more time to give equal service. This is a simple psychological fact known to anyone who has experience of different types of practice, and provision for the difference in the pay-sheet would go far to remove the present dissatisfaction and injustice. To obtain this, apart from a different capitation fee for persons of different income levels, with all the difficulties such a system would involve, the Secretary's suggestion would seem to offer the best prospect.

Nor should we be quite so opposed to payments for extra services. A high level of what is to be regarded as "general medical services" is not inconsistent with special payments for special services that a practitioner has made himself competent to render. Indeed, this is the only way to avoid the out-patient departments' being cumbered with work that can equally well be done in the surgeries, and younger practitioners' never acquiring the skill to render many services well within their potential powers. Varicose-vein and pile injections and paracentesis of the drum fall into this class, and a list could easily be drawn up that would have the general agreement of the profession and would encourage the practitioner used to giving as full a range of service as his competence allows to continue to do so, to the greater satisfaction of his patients with the State Service in which they now find themselves, and to his own added zest and profit. Incidentally, it is surprising how often State patients to-day wish they might be allowed to pay themselves for some extra service from their doctor which they have valued.

That abuses might occur is not sufficient reason for reducing general practice to a clerkship. Where are the regional medical officers who used to call and advise us on our problems under the panel, and who could surely still be chosen to carry our confidence and assist in working a Service both safe and satisfying? The fact is that psychology has been ignored—the psychology of patient and doctor alike—and variety in practice has been ignored, and until these fundamental errors are recognized and corrected the Service will not in any true sense have been born.—I am, etc.,

Wembley Park, Middlesex.

H. M. HARRIS.

SIR.—Years ago it was mooted wives and children were to be put "on the panel" at a lower capitation fee than that for the wage earners. Do I rightly remember that the B.M.A. thought this "a wrong principle," for "a wife would need just as much treatment as a husband and extra numbers did not change that fact"? Have I read letters of honoured colleagues, here and in the Dominions, affirming that justice required payment per item of service?

Is it true that practice expenses (mileage apart) are less per head for comparable service in the crowded areas? "Tell that to the marines" would be a fair if rude reply. If the ratio of expenses per head to total income is in fact less in the industrial areas, that, I suggest, is due to the miserably poor quarters in which my hard-working colleagues of slum districts live and work compared with the elegant, if not palatial, homes and gardens of many of our country brethren.

I am sorry for the rural doctor who has lost income and I would be prepared to pay to help him, but not by the foolish method of making slum practice still less attractive and increasing the imbalance in the numbers of practitioners between town and country. One of the aims of the Health Act was to redress this balance, not by forcibly shoving human beings into the arms of conscripted doctors marched into the slums, but by making conditions in these less happy districts more inviting for doctors and patients. In poor districts there is, in fact, no private practice. I doubt whether any Government

would be so stupid as to affront the sensibilities of the poor whose doctors have to have lists of more than 1,000 or 1,500 by telling them that their doctors are to be paid less, on the average, for each of them than are the country doctors for each of their patients.

Limit lists, yes, to the number which population arithmetic, decent consideration for sentimental ties, and the average doctor's energy suggest is right, and beyond that do everything to help each of us to practise medicine with the self-respect which comes from good work; but do not turn the slum practitioner into a disgruntled man by making him feel, as he sees his last few patients at about 10 p.m., that he is getting less and less for more and more.—I am, etc.,

London, S.E.16.

J. A. GILLISON.

SIR,—In the *Supplement* of Jan. 15 under "The Secretary Reports," correspondents are invited to discuss the question of a graduated capitation fee. I am delighted that the B.M.A. is open to reconsider its former attitude to this question, as I feel sure that the adoption of such a method of payment would go far to solve our financial problems.

The present method of payment is based on the erroneous assumption that a city doctor with 4,000 patients does twice as much doctoring as a country doctor with 2,000. The error in this assumption lies in the following classes of work which the general practitioner normally does in the country but not in the town:

(a) Treatment of superficial sepsis, most injuries, including simple fractures, injection of varicose veins and haemorrhoids, circumcisions, tapping hydroceles, etc., which the city doctor sends to casualty departments

(b) The simple diagnostic investigations for which the city doctor uses hospital out-patient departments.

(c) The in-patient work in cottage hospitals (excluding specialist work) for which the payment by the regional boards is quite inadequate

I think it would be deplorable if this essential and natural difference between town and country practice were wiped out by the present unimaginative method of payment. The desire, or otherwise, to do as much as possible himself is an important factor in a doctor's choice of practice; and for a country patient to have to travel fifteen or twenty miles to the nearest casualty department to have his whitlow opened or his baby circumcised, because his doctor now has too many patients to spare the time to do it himself, would be a real hardship.

I certainly do not wish to see the idle or incompetent man subsidized by his colleagues, but I do think that some help should be given to the man starting in a new practice, whose difficulties are now very great indeed. I suggest therefore the following scheme of payment:

- (1) Basic salary for the first three years in practice, payable automatically, as a matter of right.
- (2) Standard capitation fee for the first and third thousand.
- (3) 175% of standard capitation fee for the second thousand.
- (4) 25% of standard capitation fee for the fourth thousand.
- (5) Really adequate mileage.
- (6) Higher payments by regional boards for staffing general-practitioner hospitals.

If the standard capitation fee is correctly linked to Spens the above method of distribution should give fair remuneration to all.—I am, etc.,

Ilfracombe, Devon.

A. STORMONT.

SIR,—Everyone should read Dr. C. W. Warner's letter (*Supplement*, Feb. 5, p. 59). Very clearly and rightly he draws our attention to the evil that results from the present capitation system. If we are to retain such a system of remuneration at all, as Dr. Warner points out, it must be graduated to increase the income of those with relatively small lists. This is an economic necessity, but it is even more important that we should break away from the damaging conception that a doctor's work can be valued everywhere by the simple addition of the numbers for which he has undertaken to be responsible.

The same number of the *Supplement* contains an account of Dr. Charles Hill's address to the Metropolitan Counties Branch, with his answer to a questioner in which he is so rightly insistent that we should demand nothing more or less than the

application of Spens. However, the application of Spens may not be so simple. In the first place it is difficult to ascertain just how far Spens is actually being applied at any given time. Then if remuneration is found to fall below the standard there is much more loss before it can be corrected. Worst of all, to secure such correction it looks as if the profession is now to be involved in a series of plebiscites and strikes which will lower its prestige and eventually give the public an excuse for complete nationalization and utter degradation.

Apart from several adjustments, including graduation, the capitation fee should be permanently attached to every known factor that affects the general level of professional remuneration. Then the onus of constant checking and vigilance to see that Spens is applied should not fall entirely on the profession. Its application should be automatic and all variations applied to the quarter's or year's remuneration, retrospectively if necessary.

The main difficulty at present in the way of all this is the profession's pathetic clinging to a handful of private patients. The Minister can always claim that any doctor with a small list is spending his time on private work rather than giving a correspondingly greater degree of attention to each *caput*. Public appointments need present no difficulty, as these could be assessed at so many *capita* apiece both for purposes of graduation and for the overall application of Spens. It is to be hoped that some such step will shortly be taken to secure the status of our profession for all time, yet if our leaders prefer to wage a constant battle to keep remuneration abreast of varying circumstances we must on every occasion support them to the extent of striking if we are not to be worn down to the status of pre-war farmers.—I am, etc.,

Eye, Suffolk.

J. SHACKLETON BAILEY.

Private Patients at Health Centres

SIR,—I venture to suggest that at some B.M.A. meeting in the near future some such resolution as the following should be discussed—and I hope adopted.

That it is the view of this meeting that the Minister of Health is acting in a despotic, inequitable, and contemptible manner in denying to certain citizens the right of access to health centres and the right to the provision of drugs by the State, for both of which rights they pay specific taxes.

This meeting presses for strong action to be taken in the House of Parliament to remedy these injustices from which some of His Majesty's loyal subjects now suffer.

I understand, Sir, that at the last Conference of Local Medical Committees the question of the right of private patients to attend at health centres was brought forward by delegates from Birmingham. I believe the matter was not strongly pressed because it was felt it might be to the advantage of the doctor if his private patients did not have access to any health centre. If this is true, Sir, it is a deplorable example of the philosophy which is destroying us. If we continue to decide the rights and wrongs of a matter according to its good or ill effect upon our own financial well-being we are indeed doomed to yet deeper degradation than we have yet suffered; and how seldom matter affecting us are ever discussed from any other angle is revealed by a glance at any issue of the *B.M.J.*

This question of the provision of drugs for private patients and their right to all the facilities for diagnosis and treatment available to the general public, is a matter of justice and right and should be dealt with accordingly, and not at all—either by us or by the Minister of Health—from any financial aspect.—I am, etc.,

Stafford.

JOHN FREW.

Frustration

SIR,—The National Health Service is now a *fait accompli*. We have lost the right to practise where we like without the permission of the local executive council; we cannot buy or sell the goodwill of a practice; we can only claim compensation for our loss of goodwill of our practices when we resign from the Service, and this most of us cannot do. Our young doctors have more than considerable difficulty in finding suitable posts.

We have been asked by our leaders to make this National Health Service a success, and this, I am sure, all reasonable

and conscientious doctors have tried to do; but now, at the end of six months of a National Health Service, can we truthfully say that the average general practitioner is happy and contented in his work? Financially many are better off, others are worse off. In many, however, he is better or worse off, a subtle psychological change has taken place. There is a "to tell with it all" attitude of mind. "Why bother? Let them have what they want, and don't let us have an argument." And why this feeling of frustration and weariness? Our dental colleagues do not suffer from it: they are happy in their work and feel it is worth while practising conservative dentistry. Why? Because they have been adequately paid for their services. The average doctor is frustrated because he feels he is being exploited and there is nothing he can do about it. True, by increasing his N.H.S. list to a size which he is incompetent to deal with, he can make a good living. He might even employ an assistant to relieve him of some of his work, but a large list is still necessary if he is going to pay that assistant's salary. He can cut down his list to a reasonable number, but if he has no private practice to augment his income his former standard of living must be reduced.

There is going to be a Special Representative Meeting in March to discuss remuneration. Before this meeting, do let us forget about the recommendations of the Spens Report. After all they were only the incomes of various percentages of doctors of different age groups and in various conditions of practice. These in many cases were based on the incomes of N.H.I. practices, which were subsidized by good private practices in the days of private enterprise. Now the whole situation is changed, and no matter what service we give and what type of waiting-room and other amenities we provide for our patients' comfort we are all paid alike. Private practice has in many parts of the country ceased to exist.

Before this Special Representative Meeting in March let all the Divisions in the country be of one mind and instruct their representatives to demand an adequate capitation fee for every doctor no matter where he practises. Let that fee be 30s. per patient for the first 2,000 patients on the doctor's list, and a reduction for every 500 on the list above that number, so that it would not be worth while for anyone to take more patients on his list than he could attend to. Such a scheme would avoid our younger and impecunious colleagues being exploited as assistants in practices with huge lists, and would perhaps enable some of them to set up in practice on their own in what might then become "under-doctored" areas if lists were limited. It would also encourage our senior members to take the younger men into partnership.

Let us know what we want, and be determined to get it or resign from the Service, lest the standard of medicine we have been accustomed to in the past be lost for ever.—I am, etc.,

Aberdeen.

D. McLELLAN.

Fees for Advising on Films

SIR,—Are doctors acting as expert advisers in the production of films entitled to charge fees for services rendered? This question was recently discussed by the Medical Committee of the Scientific Film Association. The committee considered that heavy and onerous work, involving considerable expenditure of time by the expert, was inevitable in the making of a film, and unanimously passed the following resolution:

"Medical experts who give advice and assistance in the production of films are entitled to charge fees."

—I am, etc.,

KENNETH GOADBY,
Chairman, Medical Committee,
The Scientific Film Association.

Demands by Telephone

SIR,—Is there anything the B.M.A. can do to stop the scandalous and degrading practice the public have been encouraged into by the N.H.S. scheme of phoning up their doctor and calling out a monotonous list of articles they would like him to send on a prescription by post, as if he were a grocer or fishmonger? I am losing a number of registrations almost every week merely because I refuse to act as their stooge. Is there nothing the B.M.A. can do to defend us from this dreadful state of affairs where any unscrupulous member

of the public can blackmail a doctor with the implicit threat, "Either you put down what I tell you, or I'll take my card away and let you starve"?

What a brilliant victory we have won according to some of our representatives! Victory indeed!—I am, etc.,

London, N.W.4.

G. DAVID.

Public Health Salaries

SIR,—The proposals of the B.M.A. Negotiating Committee on public health salaries (*Supplement*, Jan. 29, p. 45) are very interesting, but I think you have made a mistake in including the 20% betterment factor, for several reasons.

(1) Whatever you say, it encourages the Ministry to think you will accept it.

(2) It makes it difficult to compare with the two Spens Reports, and to a casual observer makes the proposals appear higher than they are in relation to these.

(3) Further adjustments one way or the other will be made on the 1938 figures, not on these plus 20%, so 17% will have to be taken off your figures anyway when further adjustments are needed.

I think you should have put the scales at the same level as the two Spens Reports, and said that you would accept no advertisements which were not 20% above the scales. Also, why do those under Section VII (a) get £120 less than those under Section VI? Their responsibilities are as great or, I think, greater.—I am, etc.,

Yelverton, Devon.

JOHN SLEIGH.

Red Tape

SIR,—The other day I came across a beautiful example of red tape, ideally designed to steal the doctor's valuable time. I ordered the other day a massage for a patient, a man of about 65 who is suffering from neurovascular disturbance in his legs, due to which the patient occasionally finds himself unable to walk. I believe that this complaint is also called intermittent claudication. To help the patient I informed the massage clinic that he should have treatment at home. I was informed, however, that treatment at home could only be prescribed by a specialist. In this case I did not consider it necessary to consult a specialist as the case was quite clear to me, and I cannot possibly see any useful purpose served in wasting the specialist's time just to get his signature to another superfluous certificate required by our masters and rulers.—I am, etc.,

Welwyn Garden City, Herts.

E. JACOBS.

Abolish Assistantships

SIR,—I wish most heartily to endorse the views expressed by "Assistant" (*Supplement*, Feb. 5, p. 64). The Association's interest in the younger members of the profession has always been minimal. The type of abject slavery euphemistically termed "assistantship" is a disgrace. Unfortunately, instead of our enlightened rulers seeking to eliminate the practice, they have created in the N.H.S. a system which makes it extremely difficult for a young doctor to start as a principal.

The entrant into general practice (and it should be borne in mind that he will often have been qualified for five or even ten years) is often forced to sell his personal life and professional soul to an older man with no hope of redemption for many years to come. Is this the victory for professional freedom that the Association claims to have gained?—I am, etc.,

"ANOTHER ASSISTANT."

Delayed Settlement

SIR,—Dr. J. V. Cope writes (*Supplement*, Feb. 5, p. 60) that it is time our leaders realized the urgency of our position. That they do not do so is emphasized by Dr. Hill's comment (p. 55) that the extension of provisional terms for a further three months after March 31, 1949, is inevitable. It may be inevitable now, but it should have been averted by resolute action on the part of our leaders as early as March, 1948. Patience in negotiation is not a virtue when it is exerted at the expense of tactical position.

The immorality of the present situation appears to have escaped notice. Large numbers of doctors, on release from the Services, accepted appointments on a temporary basis (the position of the "£1,000 p.a. specialists" is by no means unique). That the pay was inadequate was acknowledged, but correction,

in accordance with the Spens Report, was promised for Jan. 1, 1948, at the inception of the N.H.S. On Jan. 1, 1948, the N.H.S. was put back to July 5, and on July 5 doctors were asked to continue on a temporary basis. Now a further delay of three months is proposed and cannot be gainsaid.

While cleverly hooked holders of temporary posts contrive a hand-to-mouth living, the economic situation of the profession as a whole deteriorates steadily. Gone is the stability of pre-N.H.S. days when an increment of remuneration came from independent sources. The Government holds hundreds of thousands of pounds of doctors' money—free of interest, be it noted—and possesses the power to say how much will be paid back. Surely this is immoral.

The longer settlement is delayed the more precarious is the profession's position. What then if the ultimate proposals are unsatisfactory? Are doctors in a position to refuse the only terms which may make them financially solvent? The majority will be subject to crushing coercion by the Ministry and forced to accept terms which it appears may be very different from those mooted in 1948.

One may well ask how the situation has arisen. Is it merely the ineptitude which has characterized all other schemes of nationalization, or is it a deliberate expedient on the part of the Ministry? Whichever it is, it bodes ill for the profession, yet our so-called leaders appear to do nothing to fight this development.

The situation is strongly reminiscent of the "phony" war. Should we not say to our leaders—as did the Parliamentarian of those days—"In the name of God—go"? Men with the courage to face and act up to these responsibilities which nationalization has placed upon us are needed to protect the future of this profession.—I am, etc.,

Burton-on-Trent.

R. LUNT.

Pay for Holidays and Overtime

SIR.—There seems to be unanimous agreement among doctors that our rate of remuneration is inadequate. That is obvious from the correspondence columns of the *B.M.J.* But is the general public also convinced of this important fact? I very much doubt it, judging by the poor support we have received from the Press over this issue.

Recently it was announced that the health services have cost £58 million more than estimated, and that the Opposition in Parliament threatened a vote of censure because of this extravagance. Is it likely in this atmosphere that the Government will suddenly decide to increase the doctors' pay and further swell the growing expenses of the Health Service? One cannot help feeling sceptical about it.

Now that doctors have been degraded to the status of Civil Service clerks we must be prepared to be treated as such by our lords and masters. Complaints of our poor pay are not likely to be sympathetically received at a time when it seems fashionable for everybody to demand more pay and less work.

On the appointed day itself, when Utopia began, Mr. Bevan informed us that Conservatives were less than vermin. I should think that the great majority of doctors were, or at any rate are now, Conservatives in their political outlook. The conclusion is obvious. Why should we, less than vermin, dare to demand an increase in pay?

There are other demands we could make which are also very important and which would certainly receive more support from the Press. The first of these is holidays with full pay. This surely is an obvious privilege now that we are Civil Servants. It is most unfair that doctors who go on holiday still have to pay for locums. Can we imagine other Government employees being denied holidays with pay? They would soon go on strike if they were. I feel the B.M.A. should press this claim on the Government with all the vigour at their disposal and at the same time enlist the support of the popular press.

Secondly comes the question of hours of work. Why not an eight-hour day with extra pay for overtime? The details might be difficult to arrange, but in this age of ubiquitous planners it is surely not beyond the resources of the powers that be. As a corollary to this of course comes the five-day week with double pay at week-ends.

Thirdly, as we are Government employees, should not our surgeries and equipment be provided for us? The wonderful

new health centres were one of the lures of the N.H.S. Where are they now? Why doesn't the B.M.A. make more of a fuss about it? It was a false promise which the Government have no intention of fulfilling.

Finally, as cars are essential to our work, the expense of buying and running them ought to be paid for, and also a servant provided to look after the surgery and answer callers and the ever-ringing telephone.

These are issues in which we can expect the support of the general public and the Press—far more than bleating about our poor pay. What about it, B.M.A.?—I am, etc.,

Sheffield.

CLAUD C. M. WATSON.

Constitution of B.M.A.

SIR.—I am aghast to see it reported that at the Special Representative Meeting on March 30 there will be a proposal to form a "medical trade union." The medical profession, composed of men and women professing the highest ethical standards, cannot be a trade, for it demands that everyone shall give of his best without any regard to future remuneration for himself. There can be no first-class, second-class, or third-class patients: all must receive the best possible advice and treatment. This profession takes no regard of race, class, or creed. All patients are professionally equal in the doctor's sight. Up to the present time the doctor has been indispensable to the whole community in that without reasonable health life is but misery and travail.

Trade is essential and honourable, but it is not a profession. Therefore I would urge that the word "trade" be eliminated from any title associated with the medical profession. Being faced, as we are now, with enormous expenses and poor receipts, let us not submit to being demoralized by commercialism, for that would soon bring us down to ruin.—I am, etc.,

London, W.1.

WILLIAM IBBOTSON.

POINTS FROM LETTERS

Practice Earnings

Mr. DONALD M. O'CONNOR (Launceston, Cornwall) writes: ... Dr. H. K. V. Soltan's letter (*Supplement*, Jan. 22, p. 38) led me to take careful stock of my own position last week. I paid 152 visits and rendered 158 other services, making a total of 310 services. My gross earnings under the Act are of the order of £35 per week, so that the average gross payment per service works out at slightly less than 2s. 5d. Take away practice expenses and income tax, and my rate of pay is not greatly more than one gives as a tip to a porter on "our" railways. I travelled 282 miles, for which I am being paid, thus far, at the rate of 3½d. per mile—less than the cost of running my ancient cars.

The Cost of Hospitals

Mr. A. L. R. WALTON, F.C.A. (London, E.C.2), writes: Mr. J. P. Wetenhall (*Supplement*, Jan. 22, p. 38) gives a reply to Sir Frederick Menzies, but I venture to suggest that we are not to the root of the matter. I think the disquiet expressed by Sir Frederick is even more widely shared than either correspondent has implied. But there will be no beginning of relief, much less of resolution, before a sufficient basis of fact is cleared to examine the problem with confidence. ... Your issue of Jan. 22 carries (at p. 141) an announcement or notice of *The Hospitals Year Book, 1948*, with a figure quotation from Mr. Wetenhall's Financial Review in the *Year Book* itself. "The cost of the voluntary hospitals (802 complying with R.U.S. conditions) for maintenance alone rose by 115% between 1938 and 1946." "115%" is a sure reverberator. It astonishes us as surely as we were astounded by Sir Frederick's figure of trebled and still rising bed costs; we are like to be hypnotized by it as readily as we succumbed to the term "new look." The figure is of the utmost importance. As the latest and only authoritative group figure of its kind for the whole country that is available to the medical and hospital world, it is indispensable. Since it is true, no quarrel can be had with it or with its dissemination—so long as it is adequately protected in its integrity. I find it naked as all of us were born and in far unkindlier isolation, rest of all context. So presented, to the very ends of the earth where your *Journal* serves with such distinction—and, as a country, we depend not lightly on the confidence of our friends—I think you will agree that the figure might unintentionally mislead. I am satisfied that the quoted 115% increase of expenditure was incurred on 19% more available beds, 11% more in-patients, and 12% more out-patients, as well as by the advance of prices and improvements in terms of employment that are not so little known.

SPECIAL CONFERENCE OF REPRESENTATIVES OF LOCAL MEDICAL COMMITTEES, MARCH 3

MOTIONS FROM LOCAL MEDICAL COMMITTEES

ANGLESEY: That part of any increase of the Central Fund be devoted to diminishing the discrepancy between the remuneration of the rural, as opposed to the urban, practitioner.

BERKSHIRE: That the deduction of 1/7 made from the capitation fees of a doctor receiving the basic salary be increased to 1/3.

BRIGHTON: That after the word "case" in the second line of the recommendation the following words be inserted: "subject to the substitution of the figure 185 for the figure 170 in the last line but one of paragraph 10, and."

BIRMINGHAM: That the betterment figure asked for should be 185 and not 170 as suggested in Para. 10 of Part I of the Report. This will involve alterations in Paras. 10, 11, and 12.)

That payment for mileage should not be provided from the pool, but from a separate fund.

That Para. 16 of the Report should read: "Such conclusions lead the Committee to the conclusion that 50% of the additional money made available in the central pool by the application of a proper betterment factor and the adjustment in relation to the increased number of practitioners should be devoted to an augmentation of the capitation fee for the first 1,000 on practitioners' lists."

BUCKINGHAMSHIRE: That this Conference recommends that the Spens Report be accepted as a basis and the betterment figure demanded be 85%, which is the official Government figure of the increase in cost of living at the present time over 1939 levels.

CAERNARVONSHIRE: That the betterment figure should not be less than 70%.

That the Mileage Fund should be distinct from and in addition to the Central Practitioners' Pool.

CAMBRIDGESHIRE: That, whilst agreeing with the British Medical Association Memorandum on remuneration of general practitioners, in which it is suggested that the total pool should be increased by £16 7/12 million, this Committee considers that there should be a uniform capitation fee for the first 2,000 patients and that the payments for patients in excess of that number should be steeply and progressively down-graded.

That in view of the fact that under present Superannuation Regulations no medical practitioner can qualify for a pension who was over the age of 59 years on July 5, 1948, and also that only a small minority are physically and mentally capable of continuing in active practice up to the age of 70 years under the stress of modern conditions, the Government be urged, in the public interest, at once to make provision to enable all medical practitioners who so desire to retire from active practice at the age of 65 years with a pension economically adequate.

DEVON AND EXETER: That, with the undermentioned amendments, the foregoing memorandum which is accepted as a fair interpretation of the recommendations of the Spens Committee be approved as the basis of the general practitioner case, the General Medical Services Committee being instructed to press the Government as a matter of urgency to adjust general practitioner remuneration on the basis of the memorandum, the adjustment being retrospective to July 5, 1948.

(a) that Para. 10 of M22 should read as follows:

10. What is the fair betterment figure, taking into account both factors? When the Government laid down its figure of 20% at the end of 1946 the real figure of the increase for middle-class budgets was between 45 and 50%. In other words, when the Government laid down a figure of 120 in relation to 100 pre-war, the real figure was 145. The expert's figure for 1948 is 185. To put matters right, in relation to cost of living, the figure of 120 should now be replaced by 185.

(b) that line 7 on page 4 of M22 should read:

Adjust for 98% of population.

GALLOWAY: That any loss which may be incurred by an executive council in running a vacant practice until a new practitioner has taken over should not be paid for from the Local Medical Pool.

That in determining an appropriate betterment factor account should be taken of the increased demand for services.

That for the purpose of calculating superannuation the fraction of mileage deducted for expenses should be less than the 50% as calculated at present.

That the treatment of venereal diseases is outwith the duties that a practitioner should perform for his patient by contract with the executive council and that he should be remunerated by the regional hospital board under a scheme similar to that introduced during the war by the County Councils of Kirkcudbright and Wigtown.

GATESHEAD: That in any allocation of pool increments which may be secured consideration shall be first given to practitioners with small lists, having regard to the relatively high proportion of the practice expenses in such lists, but that no final decision as to distribution be made until more concrete information is available as to the increment likely to be secured.

HASTINGS: That, with reference to Para. 20 (of M22), as certain age groups automatically require more service than others, it is suggested that all children below the age of 5 years, and all adults reaching pensionable age, should bear a higher capitation fee. In this way the difficulties of residential areas might be solved.

ISLE OF WIGHT: That this Conference approves Part I of the General Medical Services Committee's Report on the Remuneration of General Practitioners.

That this Conference, while approving in principle the recommendations of Part II of the General Medical Services Committee's Report on the Remuneration of General Practitioners, considers that the character of services rendered by the average rural practitioner *vis-à-vis* his urban colleague is not met by the present mileage fund of £2,000,000.

That this Conference is of the opinion that adequate payment for the treatment of temporary residents should be made from the Central Fund.

That this Conference is of the opinion that, if any basic salaries are found to be necessary, they should be met from the Central Fund and not from the Local Fund.

That this Conference is of the opinion that a list of 4,000 patients is too great for a single practitioner to provide proper medical services, and is therefore all the more anxious to secure adequate remuneration for smaller lists.

KENT AND CANTERBURY: That this Conference is of opinion:

(a) that the method of remuneration be immediately amended so that a practitioner with a list of 3,000 patients shall earn a gross income of £4,500 subject only to deductions for superannuation, and
(b) that to achieve this result, remuneration be by way of tapering capitation fees as follows:

For the first 1,000 patients, 35s. per caput;

For the second 1,000 patients, 30s. per caput;

For the third 1,000 patients, 25s. per caput;

For the remainder over 3,000 patients, 12s. 6d. per caput.

(c) that, subject to the foregoing, the basic salary be reserved for such new entrants to the Service and special cases as may be recommended by the local medical committees.

LANCASHIRE: That there should be an adequate Central Practitioners Pool which should be liable for the payment of capitation fees only.

That separate pools should be formed and financed by the Treasury to pay mileage, basic salary, temporary resident treatment, and anaesthetists' fees.

MIDDLESEX: That this Conference is of the opinion that the figure of 185 should be substituted for 170 in all negotiations with the Ministry of Health affecting the betterment factor in accordance with the figures quoted by the expert advisers of the profession.

That, whilst agreeing that it is necessary to load the income of doctors with small lists, this Conference does not agree that the whole of any additional money should necessarily be allotted to the capitation fee for the first thousand patients on a doctor's list.

That this Conference cannot agree that the Government's superannuation contribution shall be considered as part of a doctor's remuneration or that any adjustment of the Central Pool shall be made therefor.

That this Conference request the General Medical Services Committee to investigate the method adopted to calculate population figures and to suggest alternative methods to relieve hardship to doctors.

NORFOLK: That this meeting regrets that the General Medical Services Committee has not obtained precise figures for increase

in practice expenses, and requests that this be done as soon as possible, as such can easily be obtained and made available if of use.

READING: That since the B.M.A. has employed an expert who had decided that the betterment factor is 85%, this is the figure that the B.M.A. should demand.

That the Minister be asked to define exactly what is included in the capitation fee and that, the capitation fee having been determined, no deductions whatsoever should be made from it.

SOMERSET: That the "basic salary" be abolished.

SOUTHAMPTON: That, with reference to the figure 95% mentioned in Para. 4 of M.22, this figure should be subject to review by the General Medical Services Committee from time to time.

STIRLING AND CLACKMANNAN: That this Conference congratulates the General Medical Services Committee on their work done in preparing and submitting their report on remuneration of general practitioners.

That this Conference accepts the Committee's report in full and approves of their recommendations.

That this Conference urges the General Medical Services Committee to take immediate steps to have their recommendations put into effect, or, failing this, to place before the Minister the resignation of the general practitioners.

WEST SUFFOLK: That mileage fees in respect of maternity services should not be payable from the Mileage Fund available for general medical services.

SURREY: That, when publicity is envisaged, betterment should not be expressed as a percentage to be applied to total remuneration, but rather as one betterment figure applied to net income and another applied to expenses allowances, in order that the public may not be confused.

That the additional money made available in the Central Pool should be devoted entirely to an augmentation of the capitation fee for the first two thousand on a practitioner's list.

EAST SUSSEX: That, in view of the fact that the expert's figure for 1948 is 185 in relation to 100 pre-war, this Conference considers that the figure of 185 is the only basis of negotiation, particularly bearing in mind the hardship which is being suffered by many members of the profession at the present time in consequence of the National Health Service Act.

That Para. 10 of the General Medical Services Committee's Report be amended as follows:

- (a) In line 7 substitute the word "can" for the word "could."
- (b) Delete the words from "to put it at its lowest" to the words "is 160"
- (c) In line 17 delete the words "something between 160 and."
- (d) In lines 19 and 20 delete the words "taking the most modest view."
- (e) In line 21 substitute the figure "185" for the figure "170."
- (f) In paragraph 12 of the Report, page 4, substitute "85%" for "70%."

That a time limit—namely, March 31, 1949—be set to the negotiations between the profession and the Minister regarding the adjustment of remuneration to general medical practitioners. That the General Medical Services Committee should ask general medical practitioners to place their resignations in the hands of the Committee forthwith, and, if the time limit is exceeded without the just demands of the profession having been met, the resignations of all general medical practitioners within the National Health Service should take effect on March 31, 1949.

WESTMORLAND: That, whilst supporting the General Medical Services Committee's memorandum M.22/1948-9 and its recommendations in principle, this Conference considers that a much larger sum than £2,000,000 should be set aside for mileage payments, in view of the fact that rural practitioners are prevented from having lists as large as is possible in urban areas because of the scattered nature of their practices, and that they should be recompensed for time spent in travelling.

That, when the capitation fee for the first 1,000 patients has been increased to the figure suggested in M.22/1948-9, the basic salary should be either abolished or, in the event of its retention, paid out of the Central and not Local Pools.

That it would appear desirable to inaugurate some scheme for the protection of practices when a vacancy occurs and

delay is involved in filling it, whereby neighbouring doctors should be allowed to accept patients only on a temporary basis during the interval.

EAST RIDING OF YORKSHIRE: That "85%" be substituted for "70%" in Para. 12 of the Report.

That, whilst appreciating the achievement of the General Medical Services Committee in obtaining an increased Mileage Grant, this Conference is of opinion that it is still far from adequate.

ABERDEEN AND KINCARDINE: That this Conference considers that a graded scale of capitation fees is essential for the equitable distribution of the funds available.

LEEDS: That the General Medical Services Committee be urged to employ a firm of accountants to assist them in preparing and presenting the case for increased remuneration.

Branch and Division Meetings to be Held

BOURNEMOUTH DIVISION.—At Boscombe Hospital, Tuesday, March 1, 8.15 p.m. Dr. Charles Hill: "The Present Position of the National Health Service." Questions will be answered.

HASTINGS DIVISION.—At Royal East Sussex Hospital, Hastings, Tuesday, March 1, 8.30 p.m. B.M.A. Lecture by Dr. R. D. Lawrence: "Diabetes in General Practice."

LANCASTER DIVISION.—At the King's Arms Hotel, Lancaster, Saturday, March 5, 7.30 p.m. Annual dinner. Dr. Charles Hill will reply to the toast of "The British Medical Association."

MARYLEBONE DIVISION.—At 26, Portland Place, London, W., March 3, 8.15 p.m. Agenda: Instruction of Representatives to Special Representative Meeting on March 29 and 30. All medical practitioners in the area of the Division are invited.

MID-ESSEX DIVISION.—At Chelmsford Rural District Council Chambers, London Road, Chelmsford, Sunday, March 6, 10.45 a.m. Dr. MacDonald Critchley: "The Crimes of Dr. Marcel Petiot."

NORTHAMPTONSHIRE BRANCH.—At Nurses' Home, Northampton General Hospital, Sunday, March 6, 3 p.m. Illustrated lecture by Dr. J. Arthur Gorsky: "The Medico-Legal Investigation in some Murder Cases."

NUNEATON AND TAMWORTH DIVISION.—At Red Lion Hotel, Atherstone, Tuesday, March 1, 8.30 p.m. Dr. S. P. Meacock: "The Borderland of Medicine, Surgery and Dentistry."

RICHMOND DIVISION.—At Royal Hospital, Richmond, Tuesday, March 1, 3 p.m. Clinical lecture by Mr. Harold Dodd on a "Selection of Recent Advances in Surgical Practice." To be illustrated by lantern slides and a demonstration of actual cases.

STAFFORDSHIRE BRANCH.—At Town Hall, Crewe, Sunday, March 6, 3 p.m. Meeting arranged jointly by Crewe and North Staffs Divisions. Address by Dr. Charles Hill. All members of Divisions in Cheshire, Staffordshire, and Shropshire are invited.

SUSSEX BRANCH.—At the Pavilion, Brighton, Wednesday, March 2, 3 p.m. Address by Dr. H. Guy Dain.

WAKEFIELD, PONTEFRAC, AND CATFORD DIVISION.—At Wakefield General Hospital, Thursday, March 3, 8 p.m. Film: "Angina Pectoris." Discussion to be opened by Dr. John R. H. Towers.

Dangerous Drugs Act: Withdrawal of Authority

The Home Office announces that Dr. Alfred Leslie Clare Harrop (Leeds) is no longer authorized to be in possession of or to prescribe those drugs to which the Dangerous Drugs Regulations apply.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 5 1949

JOHN HUNTER THE OBSERVER*

BY

H. S. SOUTTAR, C.B.E., D.M., M.Ch., F.R.C.S.

John Hunter was born in 1728 at Long Calderwood, a small state in Lanarkshire seven miles south of Glasgow, near the village of East Kilbride. He was the last of ten children, of whom seven survived childhood. Of them James, fourteen years his senior, entered medicine and joined his brother William in London, only to end from phthisis a career of brilliant promise at the age of 29. William, ten years the senior of John, was for five years a student at Glasgow, and at first was destined for the ministry. When he was 19, however, he joined Dr. William Cullen, who at the age of 27 had a busy practice at Hamilton, near Kilbride. They must both have been young men of enterprise, or they arranged that in each winter one of them should study medicine in Edinburgh or Glasgow while the other carried on the practice. In 1740 William Hunter attended Alexander Morris's lectures in Edinburgh, and in 1741, at the age of 23, he made up his mind to seek his fortune in London. Cullen went to Glasgow, where he became Professor of Medicine; but a few years later he moved to Edinburgh, occupying successively the Chairs of Chemistry, Institutes of Medicine, and the practice of Physic, and left a high reputation as a lecturer renowned for the clearness of his exposition.

William Hunter lived at first in London with Dr. William Smellie, another Lanarkshire man and a friend of William Hunter's. Smellie had settled in London at the age of 42 after studying in Paris, and was just entering on a distinguished career in midwifery. He gave lessons in the art, using a real pelvis lined with leather for practical demonstration, and he was one of the first to stress the importance of accurate measurements. William Hunter remained with him only a short time, and became assistant to Dr. John Douglas and a surgeon's pupil at St. George's, where he worked in the dissecting-room. He visited Paris, and it is evident that he made great progress in anatomy, for in 1748 he established his own dissecting-room and advertised a course of lectures.

A Gift from Heaven

It was at this juncture that he was joined by his brother John, a raw red-headed Scottish boy of 20 who had so far given no signs of any ability, who hated books, and who was as evidently regarded as the black sheep of the family. To the amazement of everyone he settled down to his new life in the dissecting-room as one born to it. He produced beautiful dissections and delighted his brother William. He was rapidly making his way in the field of midwifery and to whom this unexpected assistance must have seemed a gift from Heaven. At the same time he was a rough

customer, and a curious point in his favour was that he was a favourite with the resurrection men, upon whom the dissecting-room was dependent for materials. It must have been a rough place, for all modern antiseptics and preservatives were unknown, and dissection under such conditions was both unpleasant and dangerous and could be carried on only in the winter.

It is worth while pausing for a moment to consider these young men, Smellie, Cullen, and the two Hunters, and the country of their origin. Glasgow itself was only a small town of 15,000 inhabitants, and the corner of Lanarkshire from which they all came must have been primitive in the last degree. Beyond this stretched the Highlands, a country without roads and in a state of barbarism beside which Afghanistan would seem civilized. Moreover, just before this, in 1745, the Highlanders had invaded England in a destroying horde, pillaging Glasgow itself and all the surrounding country on their way. It was such an environment, and not the quiet amenities of a university town, that threw up four of the greatest leaders in the history of medical science.

Hunter's Medical Pupilage

In the summer of 1749 by his brother's influence John Hunter, now 21, became a pupil at Chelsea Hospital of the great Cheselden, now nearing the end of his career. On his death in 1751 Hunter became a surgeon's pupil at St. Bartholomew's Hospital, where Percivall Pott was rising to fame. Finally, in 1754 he returned as a pupil at St. George's Hospital, where he was afterwards to serve as a surgeon for twenty-five years. In 1756 he was appointed house-surgeon, but after five months he gave it up in order to devote his time to anatomy. His interest now extended to the anatomy and physiology of the whole animal world, and he worked from morning to night dissecting every animal he could find. Naturally his health gave way, and in 1760 after an attack of inflammation of the lungs he obtained a commission as staff surgeon in the Army and saw three years of foreign service at Belleisle and in Portugal. His health recovered, and in 1763, at the age of 35, he returned to London and set up in practice as a surgeon in Golden Square.

While waiting for practice he again established a dissecting-room and a school of anatomy, devoting the greater part of his time to preparing specimens and teaching students. In order that he might also study living animals and their functions he took a plot of land "two miles from London at a place called Earl's Court," and there he built a small house in which he could indeed live but which was the centre of a most extraordinary zoo.

*The Hunterian Oration delivered before the Royal College of Surgeons of England on Feb. 14, 1949.

Over the front door was the wide-open mouth of a crocodile. In the garden were many strange animals, including a couple of leopards and a pair of buffaloes which were occasionally put into harness and driven round London. A jackal, a zebra, an ostrich, a young bull, and many smaller animals all lived together in perfect harmony.

It was scarcely an orthodox way to develop a surgical practice, but he was acquiring a vast knowledge of comparative anatomy, and his contribution to this new science was recognized in 1767 by his election, at 39, to the Royal Society. In the same year he ruptured his tendo Achillis, and this irrepressible man not only treated himself successfully on ultra-modern lines but performed a whole series of experiments on dogs to see how tendons united. Next year he was elected a surgeon on the staff of St. George's Hospital, and he now moved to his brother's old house at 42, Jermyn Street. It was a good house, suitable for a surgical practice and into which he could take, as was the custom, a number of pupils in surgery. Among his pupils were several who rose to great distinction, and we find the names of Astley Cooper, Abernethy, Clive, and Edward Jenner. But it must have been a strange house, for already Hunter's one absorbing interest was in his collection. It grew until every available room was filled with strange specimens, dry and bottled, covering the whole animal and vegetable kingdom, whilst in the passage a giraffe appeared to be emerging from the floor below. How a surgical practice could be developed under such conditions is a mystery, but it gradually grew to large dimensions. Practice was, however, always a secondary consideration, and every penny that could be spared went to the collection.

Hunter's Daily Life

Of Hunter's daily life Ottley has given such a perfect description that I cannot do better than to quote it.

"He commenced his labours in the dissecting-room generally before six in the morning, and remained there till nine, when he breakfasted. After breakfast he saw patients at his own house until twelve, when he made a point to set forth on his rounds, even though persons might be waiting for the purpose of seeing him. . . . He dined at four, then the fashionable hour, and gave strict orders that dinner should be ready punctually whether he was home or not. He was a very moderate eater, and set little value on the indulgence of the palate. During many of the later years of his life he drank no wine, and very seldom remained long at table after dinner, except when he had company. After dinner he was accustomed to sleep for about an hour, and his evenings were spent either in preparing or delivering lectures, in dictating to an amanuensis the records of particular cases, of which he kept a regular entry, or in a similar manner committing to paper the substance of any work on which he chanced to be engaged.

"When employed in the latter way, Mr. Bell and he used to retire to the study, the former carrying with him from the museum such preparations as related to the subject on which Hunter was engaged. These were placed on the table before him, and at the other end sat Mr. Bell, writing from Hunter's dictation. The manuscript was then looked over, and the grammatical blunders, for Bell was an uneducated man, corrected by Hunter. At twelve the family went to bed, and the butler, before retiring to rest, used to bring in a fresh argand lamp, by the light of which Hunter continued his labours until one or two in the morning, or even later in the winter. Thus he left only about four hours for sleep, which with the hour after dinner was all the time he devoted to the refreshment of his body. He had no home amusements, no cards, for the relaxation of his mind; the only indulgence of this kind he enjoyed consisted in an evening's ramble amongst the various denizens of earth and air which he had congregated at Earl's Court."

It was about this time that Hunter, at the age of 43, married Anne Home, the daughter of an Army doctor and

29 years of age. She was a woman of great charm and considerable social distinction, the friend of Haydn, Madame d'Arblay, and Mrs. Montague. She was something of a poetess, and wrote the words for Haydn's *Creation* and the song "My mother bids me bind my hair," which in Haydn's setting is immortal. She must have had a difficult life, but she was devoted to Hunter, and her appreciation of his work is shown in her touching epitaph inscribed on his memorial tablet in St. Martin-in-the-Fields. Only two years after their marriage Hunter at the age of 45 had his first attack of coronary thrombosis, and though he made a good recovery the fear of angina shadowed the rest of his life. It only drove him to greater efforts to complete his work, but, whilst his indomitable courage demands our unstinted admiration, perhaps we owe a greater debt than we realize to Mrs. Hunter in the background.

In 1783 the lease of his house in Jermyn Street came to an end, and he bought the lease of a large house on the east side of Leicester Square and a house behind it in Castle Street, now Charing Cross Road. On the ground between the two he built a lecture room and a museum large enough to house his immense collection. In the Leicester Square house were his consulting-rooms, whilst the Castle Street house was devoted to dissection and the preparation of specimens for the museum. This back entrance must have seen some strange sights, from the visits of resurrection men to the arrival from Earl's Court of the skeleton of O'Brien, the Irish giant, which now stands beneath this very roof. A vast staff was employed, and between the cost of this and the cost of the building Hunter expended on his collection more than £70,000. For two years this extraordinary man lived and worked in these extraordinary surroundings, a constant sufferer from attacks of angina, and in the end, at the age of 65, its victim.

Hunter's Outlook

John Hunter was above all things an observer. He was devoured by a passionate desire to know how things were made and how they worked, and it was typical of the man that he realized that the only way to do this was to look and see for himself. Indeed, he summed up his whole outlook on life in his famous aphorism, "Do not think. Try. Be patient, be accurate." To us who grow from our cradles in a world of laboratories and research it is difficult to realize how revolutionary such a proposal must have seemed to his contemporaries. For most of them all knowledge was contained in tradition and there was something almost indecent in attempts to dissect Nature. To doubt the word of Aristotle was as perverse as to doubt the book of Genesis and was to uproot the foundations of all human knowledge. It is a mistake to suppose that the objections centred only on human dissections and the resurrection men; they went far deeper into resentment at any interference with what were regarded as established facts.

It was through this veil of prejudice and ignorance that John Hunter and his museum tore so completely, and it is this achievement which so amply earns our gratitude. The specimens in his collection are themselves of value, but of greater moment is the lesson they teach us of the value of observation.

The Value of Observation

What precisely do we mean by observation, and where lies its value? In a sense every one of us is the product of observation, for each of us is moulded by his reaction to environment. But scientific observation means something more than this. First of all it means inquiry, and inquiry means that we have asked a question. Something

has happened that we do not quite understand and our curiosity is aroused. We try to produce the same event and to follow the train of circumstances which led to it. Then—and it is here that the genius of the observer appears—we modify the circumstances and see the effect upon the result. Nine times out of ten they all fit together into well-known categories, and, though our curiosity is satisfied, that is all. But just once in a while things do not quite fit together, and then if we are fortunate and have infinite patience and persistence we may find a chink through which we may peer into one of Nature's secrets. Let me give you some examples.

In 1785 Henry Cavendish by passing an electric spark through common air succeeded in getting the oxygen and nitrogen, substances with which he was only vaguely acquainted, to combine together to form nitric acid. There was, however, a small residue, less than 1%, of gas left, which he surmised might be a gas of a different nature. A century passed before Lord Rayleigh astonished the world by the discovery of argon, the unknown residue which Cavendish with his primitive apparatus isolated. His observation was perfect, but no means then existed for its interpretation. Yet the observation itself was well worth while. The foundation of a building must be laid before the keystone is placed in the arch.

You are all familiar with the spectrum, that single octave in the vast range of ether waves which we call light and by which we see the world around us. To most of us it is just a series of brilliant colours, but to the physicist it consists of a vast number of narrow lines, each the product of a single length of wave, of a single pure tone in the harmony of light. These lines form definite groups, and each group is the luminous signature of a burning element which by this signature can be identified even in a star a million million miles away. Thousands of these lines had been measured so that their position was known with extreme accuracy, but in spite of endless attempts no connexion between these measurements could be discovered.

In 1885 a little Swiss schoolmaster in Basle named Balmer felt an urge towards research in physics and consulted Professor Hagenbach about what he should do. The professor, with a smile I imagine, suggested that he should find the relation between the measurements of the four principal lines of hydrogen. The wave numbers of these lines—that is, the number of waves in a centimetre—are 15,233.22, 20,564.79, 23,032.54, and 24,373.06.

It did not seem a very hopeful problem, but to the amazement of everyone Balmer returned in a few days with the answer. If you divide all these numbers by 109,677.69 the result can be written in the simple form: $(1/4-1/9)$, $(1/4-1/16)$, $(1/4-1/25)$, $(1/4-1/36)$. Obviously these are only the first four of a series, and since his time fifty more lines have been discovered, each taking its exact place in the series. Moreover, this curious number—109,677.69—is the magic key to the place of every line in every spectrum. It is now known as Rydberg's constant, and with it Niels Bohr, the great Danish physicist, was able to unravel secrets of atomic structure which have revolutionized our whole conception of matter. But it was Balmer who found the key.

In 1900 Crookes devised a toy in which a minute speck of radium was placed in front of a tiny fluorescent screen. On looking through a lens you saw a shower of bright sparks. A young physicist named Rutherford from the backwoods of New Zealand was intrigued by this and took the trouble to count the sparks under varying conditions. They proved to be the key to the secrets of radium and of atomic changes until then unknown, secrets which have already produced the atom bomb and which if they do not destroy us must certainly revolutionize our lives.

Some twenty years ago Alexander Fleming found a spot of mould growing on one of his culture plates, and he noticed that none of the bacteria in culture grew near the mould. Overcoming his natural resentment at such an impertinent intrusion into his laboratory by a mere mould, he studied

the intruder and found that it possessed the very remarkable power of preventing bacterial growth. He suspected that this might be due to some chemical substance secreted in the mould, but he had to wait over ten years for this substance to be isolated by Florey and for the discovery of penicillin.

Now in each of these cases the first observation was a simple matter: the genius of the observer lay in his appreciation that there was something here which he did not understand, some new fact outside his experience. He has found a door, but he does not know where it may lead and he cannot open it until he has found the key. But the observation was the first step, and without it the door would never have been found. And the initial observation is often so trivial that for most of us the event would have passed unnoticed and the observation never have been made at all. Think of Cavendish with his primitive globes of gas: the little Swiss schoolmaster with his incomprehensible figures; Rutherford and a few sparks; Alexander Fleming and a spot of mould on a culture plate. Yet each was peering through a tiny window into a new world.

It is, however, only very rarely that the power to make observations and the ability to unravel their meaning are combined in the same individual, or, indeed, that both can be accomplished in the same epoch. As we have just seen, years may elapse between the observation and the full appreciation of its meaning. It was in observation that Hunter was supreme, and, although within the limits of his time he often made acute deductions from his observations, his records are still worth our study as examples of what can be done with little more than unaided eyesight.

The Background of Observation

With such a great example before us I feel that it will be worth while to devote a few moments to consideration of "observation," to see in what it consists, to study its uses, and to examine how such power can be acquired and developed. In a sense our whole lives are spent in observation, for when you come to examine it you will find that our every action is a result of some stimulus and a reaction to environment. But this is not quite what we mean by conscious observation. Surrounded by a vast stream of events, of which fortunately we can appreciate only a minute fraction, we sometimes actively direct our attention to some detail which has aroused our interest. What is involved in such attention and under what conditions can it serve a purpose?

The mere fact that our attention has been attracted shows that something unusual has occurred either in the external world or in its impact on our mentality. It is usually the latter, for Nature is very conservative and rarely allows a variation, but in any case the important fact is that to us the event was exceptional. I suppose that for countless aeons of time men watched the stars stream across the sky before one of these men noticed that one of the stars had moved from its place. But notice that that man himself must have watched the stars for years till their permanent relation was fixed in his mind and he was startled to find that one had changed its place. You can imagine that he kept the secret to himself and watched night after night to see if it were really true. And if he were a wise man the more certain he became the more closely would he guard such a revolutionary discovery.

You see, then, that observation itself demands a background of conscious knowledge. Our first astronomer saw the stars as other men saw them, but with this difference—that up to the moment of his great discovery he realized that they all kept their appointed stations, night after night and year after year. Without that background his observation would have been meaningless: with that background

it was a discovery which marked an epoch. The first-essential of all useful observation is, then, a background of established knowledge—that is to say, that on our memories is imprinted a pattern to which events around us conform, arousing our memories, perhaps, but without disturbing the pattern. In most of us the pattern becomes so fixed that variations pass unnoticed, and indeed since events are never exactly repeated such assimilation of variation is essential if the pattern is to remain. But then one day we become conscious of some variation, perhaps because of its insistent repetition. Our interest is aroused and we stir ourselves to active observation.

Curiosity an Essential Factor

Here men are divided into two great groups, the incurious and the curious. Of the causes of the divergence we know nothing; perhaps it is based on some endocrine or nutritional factor; but, however that may be, we all recognize the man to whom discovery is the breath of life and the man to whom it is anathema. The latter is often a first-class teacher who not unnaturally fears the disturbance of his mental categories; the former may be a great researcher but is often entirely unintelligible to his pupils because he can never keep clearly before them the picture they require, since his mind is too fluid. Just occasionally you find the rare mind with a clear picture but a burning curiosity which can inspire the pupils as well as the teacher.

I should say, then, that one essential factor in observation is curiosity. There are many kinds of curiosity, from the mere desire to interfere, with which we are all familiar, to the urge to satisfy some deep longing for comprehension, to resolve a discord in a final harmony. Whatever its true nature it is undoubtedly an instinct essential for fruitful observation and one with which every teacher should seek to inspire his pupils. In John Hunter it was almost a mania, and it was the steady driving force behind all his work.

A background of knowledge, curiosity, and the desire to extend that knowledge are thus essential for fruitful observation, but something more is still required—the training of the power of observation itself. For the mere act of observation is not a simple act but a highly complex process in which many factors are involved, and in the trained observer all these factors are subconsciously combined into a perfect unity, so perfect that its complex origin is concealed from the observer himself.

Each of us is given at birth eyes, ears, and touch corpuscles in his fingers. Over these primary organs of sense we have little influence; fortunately we have little if any power of modifying their structure, and they do not appear to vary greatly from one individual to another. These different organs carry impressions to the nervous matter of the central nervous system and ultimately to the brain, the great central exchange for the correlation and synthesis of nervous impressions. Of how the brain works we know very little, but two facts appear to be well established. After a very early age its cells never divide and therefore never multiply, but they have the power of forming connexions with adjacent cells and of facilitating the passage of impulses by the reduction of the resistance at the synapse where they connect.

Trained Observation

Each of us, then, is provided at birth with sense organs which he cannot modify, and a system of intercommunicating cables along which he can transmit messages but to which he can make no addition. By constant repetition of one system of impulses, however, he can break down resistance at the appropriate synapses so that the message passes

freely and without conscious effort. We can in fact develop a trained action or acquire a habit. We can modify or combine the impressions coming in through different channels so that, far from colliding, they reinforce one another and resolve confusion into a single clear, definite picture.

It is only by such training that the power of observation in any field can be acquired, and a few examples will make this perfectly clear.

The artist has trained his eye and his hand so that they work together in perfect harmony, and while he studies his subject you can see his hand already making the movements which will ultimately convey to paper through his pencil what his eye has grasped. Do you imagine that a violinist thinks where to put his fingers? He does not think about it at all, for he knows that his ear and his fingers work together in perfect harmony and that they will give him all that he asks, whether in brilliant cadenza or in subtle tone. And yet the co-ordination demanded in the artist and the musician does not surpass that necessary to the skill of the true clinical observer.

A physician is standing by a child's bedside; his fingers are on its wrist. He feels the dry, hot skin. He notes the racing pulse and estimates its power, its quality, its regularity. He sees the flushed face with its tinge of blue; he sees the nose expanding at each quick intake; he hears the hurried respiration and its characteristic grunt. And he knows that he is faced with a case of acute pneumonia with a certainty which nothing but direct clinical observation can afford. His long experience has gathered together a great number of separate impressions into one clear picture. He is a trained clinical observer, and all his impressions are grouped together subconsciously into one observation which sweeps away irrelevant detail and grasps the one essential fact.

Perhaps I have chosen too simple an example, but the point I wish to stress is the value of trained observation and the great complexity of the factors which are involved in its achievement. I do not in the least degree undervalue the aids which science has placed at our disposal—chemical investigations, microscopical studies, and x rays, for example—but all these are details to be assimilated by the observer and brought into the general picture, for without this co-ordination they are all too likely to lead to errors.

Even elementary observation is the most difficult thing for a student to learn, and trained observation is only slowly acquired, but it is a power at which every student should aim from the first moment and of which every teacher should enforce the value. For the majority of us visual impressions are the most important, and these can be developed better and more rapidly by attempts at drawing than in any other way. However crude the drawing may be, the mere attempt enforces observation, and the shape of a bone, for example, can in a few minutes be fixed in the memory. The mere fact that one is rousing from slumber tracts in the brain so far unused means an incalculable addition to one's powers. And if one can succeed in arousing by such means a latent curiosity the trained observer is in sight.

The Teacher's Problem

This is the real problem of every teacher—how to teach his students to observe. Great variations in methods are possible, and in no field of action is there greater scope for originality, but at least in a field so complex as that of medicine certain broad lines must be followed.

First of all the student must be shown in detail all the essential elements of the completed picture which he should ultimately retain as a permanent pattern. Most of us are visualists, and only what we have actually seen leaves a permanent impression on our memories. In Continental clinics the lecture-demonstration fills a more important role than it does in this country, and I feel that we might make much greater use of it than we do. I still remember

demonstration on tuberculosis of the spine given by the late Professor Hotz at Basle. It began with a series of fine pathological preparations showing every stage of the disease, with skiagrams and photographs to show its clinical progress. A little man with an old healed angular curvature then came in, and he was followed by two bed cases, one of paraplegia and one of psoas abscess. In an hour we had been shown a complete picture of the disease so vivid that it still remains to me a living memory after twenty-five years. Such a demonstration involves resources in material and assistance which are rarely available, but can you question their incomparable value?

Next the student must have access to specimens, to microscopical slides, and to patients, so that he may study every detail of the picture at his leisure. In this College we are rapidly building up a pathological museum with this very object in view, where the student will find ready to his hand all the material for training his mind in exact observation which no book can supply. The patient himself must be studied in the hospital, but perhaps we may in the very distant future have even our own clinic for the more advanced study of disease.

With this experience behind him the ward demonstration will take on for the student an entirely new significance. Here the teacher can draw upon his own experience and illustrate the points he desires to stress from the patients around him, while the student is introduced to the human side of observation as distinct from the purely scientific.

Finally, in the out-patient department the art is acquired of rapid recognition of main symptoms and their separation from a confused mass of unimportant details. The student learns to recognize disease at sight, to become in fact the trained observer.

You will see, then, that the mind of the great observer is replete with pictures of definite entities, each a vivid and living reality based on an actual experience. It has been my good fortune to meet some of these great minds who leave so deep an impress on our own personality, and when I mention the names of Harold Barnard, Henry Head, and Wilfred Trotter many of you will be recalled to happy memories. With Barnard every case was an adventure into the world of romance, every specimen a trophy from a voyage of discovery. To Head a small area of increased sensation was an Open Sesame, a slight change in gait the key to deeply seated processes of vital import. The quiet glance of Trotter could penetrate into the subtle instincts which, to us unknown, play so large a part in all our lives. Each was a great observer and each has left for us the golden harvest of what he saw and the gleaming inspiration of his example.

In the ancient world men looked within themselves for knowledge, and for them the world around had little interest. For us a vast field of Nature has been opened of which they knew nothing, and it seems to be as limitless as the heavens. Whether we look down a microscope at a minute organism, or through a great telescope at a nebula a million years of light away, we realize that there is an infinity beyond. But, infinitely small or infinitely distant, it is there for us to see, and it only awaits our observation. All around us are whole worlds for us to see if we will only look, to hear if we will only listen.

"What does it matter where or how we die
So long as we have health to see it all—
The different ways that different things are done,
And men and women loving in this world?"

Could a better epitaph be found for the great observer we honour to-day—John Hunter?

HAEMATEMESIS

WITH SPECIAL REFERENCE TO CHRONIC
PEPTIC ULCER

BY

D. C. LEWIN, M.D., M.R.C.P.

AND

SIDNEY TRUELOVE, M.D., M.R.C.P.

(From the Radcliffe Infirmary, Oxford)

While haematemesis remains one of the common emergencies in hospital practice it is natural that its prognosis should be the subject of controversy. This controversy has been fostered by the widely different fatality rates recorded by various workers. To a great extent these discrepancies have arisen from faulty selection of data and errors in their presentation. The fallacies of many published series have been pointed out by Avery Jones (1947), and he has suggested criteria for estimating the fatality rate which if generally adopted would permit fair comparison of different series. Avery Jones has also presented the largest personal series of cases of haematemesis treated in this country, with a fatality rate of 8%. It is likely that haematemesis carries a considerably higher fatality rate in the country as a whole, for it would be absurd if a highly trained specialist did not obtain better results than less-experienced workers.

The great value of Avery Jones's results is that they set a standard which others may seek to achieve. In this connexion it is noteworthy that the literature shows that most series with a low fatality rate have come from interested single physicians presenting their own cases, whereas studies of gross hospital figures commonly indicate a much less favourable prognosis. Thus Babey and Hurst (1936), Smith (1945), and Avery Jones (1947), who report their own cases, record fatality rates of 6-8%. Conversely, recent publications of mass hospital figures show a fatality rate ranging from 13 to 25% (Chiesman, 1932; Cullinan and Price, 1932; Burger and Hartfall, 1934; Hellier, 1934; Aitken, 1934).

We believe that mass hospital figures are more truly representative of the dangers of haematemesis than are the results obtained by a few specialists, provided that the data are handled with an appreciation of possible fallacies. The one essential is that only those data which are likely to be accurately recorded in the notes should be employed. The present study shows that haematemesis remains a highly dangerous condition.

Data

The sources of data of this study are the in-patient notes of the Radcliffe Infirmary, a general teaching hospital in a half-rural, half-industrial area, covering the ten years 1938-47 inclusive. Case notes of all patients admitted as emergencies because of haematemesis or melaena have been analysed. The cause of the bleeding was classified under the following headings: (1) chronic peptic ulcer; (2) acute peptic ulcer; (3) other causes; (4) unknown.

The criterion used for making the diagnosis of peptic ulcer was a record in the case history of epigastric pain with at least two of the following characteristics: (1) relationship to meals; (2) relief by food, alkalis, or vomiting; (3) periodical remissions. In addition, a history of previous perforation or positive x-ray findings were taken as strong evidence in favour of the diagnosis. Ulceration was deemed to be acute if there was no history of periodicity and the symptoms had been present for less than three months.

Fig. 1.—Whole series: fatality rate from haematemesis

(2) subarachnoid haemorrhage (30 days after admission); (3) partial gastrectomy (for perforation on 14th day after admission); (4) partial gastrectomy (51st day); (5) liver failure due to a concurrent hepatitis (31st day after admission).

Results

Table I and Fig. 1, dealing with the whole series, show the relation between age and fatality rate and demonstrate that the fatality rate climbs steeply with advancing years. There

appears to be a sharp increase at about 50 years of age, and the fatality rate of the over-fifties is about five times as great as that of the under-fifties (Table II).

Fig. 2.—Chronic ulcer group: fatality rate from haematemesis.

In considering the fatal cases we have adopted the criteria of Avery Jones (1947) in excluding only those deaths due to unrelated diseases or to elective operation after recovery from the bleeding. Those excluded were due to:

(1) pyaemia arising from a boil (44 days after admission);

cases diagnosed as proved or probable chronic peptic ulcer. A certain number of patients included in the "unknown" "acute ulcer" groups were later found to be suffering from chronic peptic ulcers. However, we have deliberately not included such cases in our chronic ulcer group for the reason that a diagnosis of chronic ulcer can always be made at necropsy, but the final diagnosis is not necessarily certain in the patient's life. In other words, to work on final diagnosis might unduly weight the "chronic ulcer" group with fatal cases. In consequence we have preferred to deal with the cases whose previous history made the diagnosis of chronic peptic ulcer reasonably certain on admission to hospital. It may be noted that no gross distortion of our main conclusion occurs if we work on final diagnosis.

Effect of Sex

Table IV shows the results of classifying the chronic ulcer group into males and females and two main age groups—below and above 50 years. Considerably fewer women than men are admitted with haematemesis due to chronic ulcer, and the discrepancy between the sexes is more pronounced in the younger of these groups. The effect of age on fatality rate appears to be similar in men and women, so that when we deal with the whole group this effect is not an artifact due to different proportions of men and women in various age groups. For comparison we have regrouped Avery Jones's data in the same way (Table V). It will be seen that a similar sex distribution occurs.

TABLE IV.—Chronic Ulcer Group Only: Effect of Sex on Fatality Rate

Age Group	Males		Females	
	No. of Patients	No. Died	No. of Patients	No. Died
<50	74	5	18	1
50+	83	26	33	7
Totals	157	31	51	8

TABLE V.—Avery Jones's Figures Regrouped as in Table IV

Age Group	Males		Females	
	No. of Patients	No. Died	No. of Patients	No. Died
<50	166	3	54	2
50+	180	25	130	12

tribution occurs. A small point worth mentioning is that among the men the proportion of patients over 50 is almost identical in the two series. Avery Jones's belief that municipal hospitals have to deal with an unduly large proportion of elderly patients therefore does not appear to be well founded.

Length of Ulcer History

Although it is well known that older patients are more prone to die from haematemesis, there is little clear evidence to show the precise reason. It is important to elucidate whether the change in fatality rate is brought about by (a) general bodily changes due to ageing of the patient or (b) local conditions in the ulcer, particularly those due to chronicity. Since a chronic peptic ulcer may persist for many years it is evident that among the older age groups there would be a large proportion of patients with long-standing ulcers. Therefore in order to separate the effects of age of patient from length of ulcer history, we have so analysed our data as to show the influence of both these factors simultaneously (Table VI and Fig. 3).

From Table VI it appears clear that the age of the patient is of profound importance and the length of ulcer history negligible. The finding is so clear-cut that it is unlikely to be an artifact. Unfortunately, previous workers have not presented their data in such a way as to demonstrate whether or not this is a general finding. It is true that Burger and Harfial (1934) mention the length of history of all their cases of peptic ulcer and of the fatal cases, but no account is taken of the patient's age. When their data are rearranged and presented as in Table VI we find that patients with a history of more than ten years have a worse prognosis than those with a history of 1-5 years, but the difference is not great (Table VII). The

Table III shows that 208 patients were classified as suffering from chronic ulcer by the criteria already given. The effect of age of patient on liability to death remains as pronounced as with the whole series, and Fig. 2 is similar in shape to Fig. 1.

In what follows we are concerned solely with the group of

FIG 3.—Fatality rate in relation to length of ulcer history and age group.

TABLE VI.—Chronic Ulcer Group. Influence on Fatality Rate of Age of Patient and Length of Ulcer History

Length of Ulcer History	Age of Patients in Years					
	<50			50+		
	No. of Patients	No. Died	Fatality Rate	No. of Patients	No. Died	Fatality Rate
5 years ..	30	3	10.0%	18	6	33.3%
5-9 ..	24	0	0.0%	22	6	27.3%
10-19 ..	22	2	9.1%	48	15	31.2%
20+ ..	12	1	8.3%	27	6	22.2%
Not specified ..	4	0	—	1	0	—
<10 years ..	54	3	5.6%	40	12	30.0%
10+ ..	34	3	8.8%	75	21	28.0%

TABLE VII.—Fatality Rate from Rearrangement of Burger and Hartfall's Data

Length of Ulcer History	No. of Patients	No. Died	Fatality Rate
1-5 years ..	51	14	28%
5-9 ..	12	1	8%
10+ ..	29	11	38%

group of patients with a history of 5-10 years is so small that little attention can be paid to its low fatality rate. When we bear in mind that long-standing ulcers are more common in older age groups the greater average age of such patients might well account for the small difference observed.

Prognostic Significance of Previous Haematemesis

A history of previous haematemesis is not uncommon among patients in the chronic ulcer group. It is naturally important to know whether or not a past history of haematemesis influences prognosis. Table VIII shows the results of comparing patients with and without a history of previous haematemesis in the two main age groups.

TABLE VIII.—Chronic Ulcer Group. Prognostic Significance of History of Previous Haematemesis

	<50			50+		
	No. of Patients	Fatality Rate	Difference and Standard Error	No. of Patients	Fatality Rate	Difference and Standard Error
With previous haematemesis	33	9.1%	4.0 ± 5.8	47	27.7%	1.3 ± 8.6
Without previous haematemesis	59	5.1%		69	29.0%	

There is no significant difference in fatality rate between these two classes of patient, but the effect of age remains unaltered. In other words, a history of previous haematemesis has no bearing on immediate prognosis. Conversely, the greater fatality rate among older age groups is not because they contain a large proportion of patients with a history of previous haematemesis.

Severity of Bleeding

In considering why older patients are more prone to die from haematemesis we must take account of the possibility that such patients may bleed more profusely or for a longer time than younger patients, possibly because their vessels are arteriosclerotic and cannot retract efficiently. It is evident that no accurate estimate of the extent of bleeding can be obtained without precise and repeated studies of haemoglobin and blood volume. Such elaborate data are not available in case notes, and we have been forced to rely upon (a) a record of repeated frank haematemesis or melaena, or of general signs of internal haemorrhage, to indicate the occurrence of further bleeding after admission to hospital, and (b) the amount of blood transfused as a rough indication of the total blood loss.

Table IX shows that while recurrent bleeding is more common in the older age-groups the difference is not great, and it is certainly not sufficient to account for the much higher fatality rate.

TABLE IX.—Chronic Ulcer Group. Frequency of Recurrent Bleeding Among Age Groups

Age Group	No. of Cases	No. with R.B.	Difference	Standard Error of Difference
<50 ..	92	28 (30.4%)	6.7	6.6
50+ ..	116	43 (37.1%)		

Table X shows the amount of blood transfused to patients in the two main age groups. If we define a massive blood transfusion as one of ten pints (5.68 litres) or more, it is of interest that in each of the age groups about the same proportion of patients received such a massive transfusion: 6 out of 92 (6.5%), compared with 10 out of 116 (8.5%). Massive bleeding is therefore not uncommon in the younger age groups, but it does not often appear to be fatal when treated with blood transfusion.

TABLE X.—Chronic Ulcer Group. Amount of Blood Transfused

No. of Bottles of Blood	Age: <50		50+	
	Cases	Died	Cases	Died
0 ..	49	0	38	4
1-4 ..	29	4	47	15
5-9 ..	7	0	18	5
10+ ..	6	1	10	6
Unknown ..	1	—	3	—

Within the limitations inevitably imposed by the nature of our data, these findings do not suggest that the greater fatality among older age groups is mainly due to more severe haemorrhage. We are thus led back to our previous conclusion that the difference is due to the general bodily changes which occur with age.

Results of Surgery

Very few cases were treated surgically. Eight patients, all over 50, were treated by emergency partial gastrectomy because of recurrent bleeding. The results were not encouraging, for five patients died. In such a small group random sampling errors may be very large, so that no firm conclusion can be drawn from this result. Six patients were treated by surgical procedures, such as under-sewing the ulcer to an artery. Among these, of four who were alive, and of two over 50 both died. We are here with the relative merits of surgical and medical treatment for which an *ad hoc* inquiry is preferable. On including these figures it is to show that the overall poor risk with haematemesis whether treated medically or surgically. More important in the present context, cases treated surgically is not large enough to draw conclusions.

Discussion

The most prominent feature of this series is the great increase of fatality rate with increasing age of the patient. This has been noted previously by many workers both in this country and in America, but little attention has been focused on the underlying reasons for it. It is conceivable that the older patients may die more readily either because the ageing organism becomes less adaptable or because local changes which predispose to massive haemorrhage may develop in the ulcer as a result of chronicity. Analysis of the present series shows that the length of history among patients with proved or probable chronic peptic ulcer has no bearing on the expectation of death, which seems to be related to general changes in the body consequent upon age. This conclusion is supported by other findings. Thus recurrent bleeding after admission to hospital occurs very little more frequently in the older than in the younger age groups. About the same proportion of young and old patients require massive blood transfusion; but, whereas the younger patients receiving massive transfusion mostly live, the older ones mostly die.

It would be convenient if we were able to compare this finding with the fatality of haemorrhage occurring from other causes, but there is no common cause of massive haemorrhage occurring over a wide age group. We have therefore been unable to seek confirmation along these lines. However, the general bodily changes induced by haemorrhage are somewhat similar to those occurring in "shock," and it is therefore of interest to examine the prognosis of perforated peptic ulcer in relation to age. Table XI, which has been compiled from the records of the Radcliffe Infirmary, shows that perforation of peptic ulcer produces a fatality rate which climbs steeply with advancing age.

It is unlikely that the local conditions in perforated ulcers can account for the great difference in prognosis between young and old patients. The marked increase in fatality rate with advancing years is therefore presumably due to changes in the whole organism. The similarity between these findings and those in haematemesis reinforces our previous conclusion that in haematemesis the poor prognosis in later life is mainly due to general bodily changes and not to local conditions.

TABLE XI.—Fatality Rate of Perforated Ulcer by Age Groups

Age Group	No. of Cases	No. Died	% Died
<30 ..	18	1	5.6
30-39 ..	34	1	2.9
40-49 ..	48	10	20.8
50-59 ..	41	12	29.2
60-69 ..	23	7	30.5
70+ ..	9	3	33.3
Total ..	173	34	19.7

Haematemesis and perforation are the commonest major complications of chronic peptic ulcer, and both are dangerous to life if they occur in middle age or later. It is natural to speculate whether patients approaching middle age with a chronic peptic ulcer should be treated by partial gastrectomy largely as a prophylactic measure. In order to arrive at a decision we must be able to weigh the risk of elective partial gastrectomy against the chance of dying in the future from haematemesis or perforation of a chronic ulcer. On the one hand, the operative fatality rate of partial gastrectomy is known to be about 5% or less in patients under 50. On the other, there appears to be no precise knowledge of the chance of developing either of these complications. With this serious omission in our knowledge it is consequently impossible to reach any valid conclusion.

Summary

Among 305 cases of haematemesis admitted to the Radcliffe Infirmary as emergencies during the period 1938-47 there were 58 (19%) deaths.

Of these patients 208 had a history of proved or probable chronic peptic ulcer. The fatality rate among them was also 19%.

Both for the whole series and for the group with chronic peptic ulcer age was the most important factor influencing prognosis. The fatality rate rose steeply in middle age.

Among patients with chronic peptic ulcer the length of ulcer history had little bearing on immediate prognosis.

The frequency of recurrent bleeding was about the same in old and young patients, and about the same proportion received massive blood transfusions.

These findings suggest that general bodily changes, and not local conditions in the ulcer, are mainly responsible for the poor prognosis in later life.

We wish to thank Mr. J. Baxter and Miss Merry, of the Records Department, Radcliffe Infirmary, for their assistance, and Professor L. J. Wills and Dr. A. M. Cooke for their helpful criticism.

PUNCH PROSTATECTOMY

BY

H. T. COX, M.A., M.D., F.R.C.S.Ed.

Visiting Surgeon, Withington Hospital, Manchester

Punch prostatectomy is a subtotal prostatectomy carried out through the urethra, thus avoiding an abdominal incision. Any paper that refers to the mortality rate for prostatectomy, by whatever method, must offer particular and precise information on at least the following points: the age and type of patient, the indications for prostatectomy, the number of permanent ambulatory suprapubic cystostomies, and whether those cases admitted with retention were subjected to early or late prostatectomy. These points largely determine mortality rates, and a low mortality rate in any series that omits particular reference to them carries no conviction; it merely reflects an accepted view that the present-day hazards of abdominal surgery in good or in moderately good risks are not high.

The mortality rate is known to be lower for private than for hospital patients. "This is due to the fact that the average hospital case is a notoriously bad risk, having neglected himself until complete retention or renal failure forces him to seek advice, whereas the private patient presents himself at an earlier and more favourable stage of the disease" (Kenneth Walker, 1933).

One may add a further and notable distinction—namely, that between municipal and voluntary hospital patients, a series of the former being heavily overweighted by physical wrecks with advanced degenerative changes and a physiological age well in advance of their calendar age. Until recent months this series has been composed entirely of municipal patients.

The safety of punch prostatectomy allows it to be performed in preference to suprapubic cystostomy, so that no permanent suprapubic cystostomies in ambulatory patients have been carried out in this series. The indications for

operation and the age of the patients are given in the accompanying Table. The routine treatment for cases admitted with retention of urine is decompression and drainage by urethral catheter, the patient being kept ambulatory during both procedures, followed by early punch prostatectomy. Complete bed-rest is unnecessary and detrimental. It should be emphasized that any statistical survey favours abdominal prostatectomy, as patients who present too great a risk for abdominal prostatectomy are accepted or transferred to the clinic for punch prostatectomy. In the Table no attempt has been made to separate the good from the bad risks—and many were the worst possible—or simple from malignant prostates. Many of the latter had widespread spinal metastases at the time of operation.

400 Cases of Prostatic Obstruction, Simple and Malignant, Treated by Punch Prostatectomy

Acute	Chronic I*	81
Chronic I*	Chronic II*	3
Chronic II*	Mixed	1
Total		254

* Chronic I and chronic II cases are those with or without urinary symptoms respectively.

Mortality Rate

First 100	15%	Third 100	2%
Second 100	9%	Fourth 100	4%

One patient aged 36, with a previous retention at the age of 31, was found to be suffering from prostatic cysts, which were successfully resected. One hundred patients were resected with the diathermy loop before this instrument was discarded in favour of the punch instrument.

One case of *post-operative stricture* at the external meatus was rapidly cured by meatotomy and bougies. There was one case of *post-operative incontinence*.

Associated vesical lesions consisted of calculi, 4; calculi and diverticula, 2; diverticula, 2; carcinoma, 1. In two cases a diverticulectomy had to be carried out.

Raised blood-urea was encountered in 27 cases before operation, as follows: 200-250 mg. per 100 ml. in 2 patients, 150-200 mg. in 3 patients, 100-150 mg. in 8 patients, and 60-100 mg. in 14 patients. Most of these raised figures fell to normal with urethral drainage immediately before operation. There were two deaths, both in the last group. The results of preliminary urethral drainage in these cases of chronic retention do not suggest that this method should be discarded in favour of prostatectomy with the bladder undecompressed.

Raised blood-pressure Estimations.—Systolic blood pressures of 200 mm. Hg or over were recorded in 43 cases. These readings were taken on the operating table immediately before operation without preceding ephedrine, and were in a few cases higher by 10-20 mm. than the resting pressures taken in bed. The highest pressure taken would not record on the 260 mm. Hg sphygmomanometer.

Mortality Rates.—The mortality rate of 15% for the first hundred is unduly high and is not likely to be repeated. It was due to a number of causes. The cases were then nursed in a chronic ward with all that this implies in a municipal hospital. The patients operated on represented in a high percentage the rejects and failures of abdominal prostatectomy—a resident or semi-resident population of aged men, some with high infected residual urines who were catheterized intermittently and others who returned to hospital at regular intervals to have phosphatic concretions

removed from their suprapubic tubes. In addition there was a varied pathological group, also of shocking risks: one patient had been bedridden for ten years with syringomyelia before developing definite symptoms of prostatic obstruction. Lack of experience with the punch instrument contributed to the mortality rate in the first hundred and to a lesser degree in the second hundred. Of the two patients dying in the third hundred, one, aged 75, had been catheterized eight times before admission and the second was aged 82. After operation the latter patient, in a moment of mental weakness and using a razor that bore excellent testimony to the standards of the Sheffield Cutlers, performed a very radical amputation of his penis and scrotum.

The relevant details of the four deaths in the last hundred are as follows: at age 67, from advanced prostatic carcinoma; at age 65, a patient with paralysis agitans, death from pulmonary embolus—the only one in the series; at age 75, transferred with suprapubic cystostomy for punch prostatectomy, emaciation extreme: at age 75, a patient catheterized six times before admission.

External Urethrotomy.—In eight cases the calibre of the urethra was so small that the instrument had to be inserted through a small urethral incision.

Prostatic Carcinoma.—There were 55 cases (approximately 14%). Of these, 51 were treated by punch prostatectomy and the diagnosis was pathologically confirmed. In the remaining four the clinical or pathological signs or the response to oestrogen therapy left no doubt about the diagnosis. As the result of rectal and radiological examination, acid serum phosphatase estimation, and posterior urethroscopy, the pre-operative diagnosis was unmistakable in 48 out of the 51 cases. The proportion of occult prostatic carcinoma was therefore under 1%. One patient died of heart failure; the remaining two, on oestrogen therapy, are still alive without evidence of a recurrence six years and three years after resection. One further fact is worthy of comment. In dealing with a moderate-sized or large malignant prostate which is hard and nodular on rectal examination the amount of tissue removed at operation before the capsule is exposed is often surprisingly small. Rectal examination after such an adequate resection exposing the capsular fibres almost invariably reveals no change whatever in the hard nodular feel. This clearly shows that the greater part of the malignant tissue is outside the capsule. As it is very rare for the maximum size of a malignant growth to be elsewhere than at its point of origin—apart, of course, from metastases—this finding is evidence that this type of carcinoma has a very high incidence of origin from the posterior lobe.

Chronic Retention.—The cases of chronic retention have been classified into groups I and II, the former with urinary symptoms, the latter without. The clinical impression derived from these cases is that, with equal degrees of a substantial renal impairment as represented by the blood-urea estimation, the prognosis is worse in group II than in group I. This is an expected finding, as group II cases tend to be more chronic than group I, and the prognosis clearly depends on the length of time the blood urea has been raised as well as the height of the rise. Sudden emptying of the bladder in late group II cases may without doubt be fatal. I believe that these cases should be treated by a very slow decompression. The urinary output for 24 hours is measured—it may be normal—and this figure forms the basis for the decompression. The decompression is started by withdrawing from the bladder in 24 hours a volume of urine which exceeds this figure by 4 oz. (114 ml.); the bladder is therefore initially being decompressed at the rate of 4 oz. a day—a rate that may have to be increased later. This method is, of course, applicable only to group II cases.

Results of Follow-up

Punch prostatectomy, being a subtotal prostatectomy, is associated with a small recurrence rate, which in the hands of an expert employing the operation in nearly 100% of cases should be less than 3-4%. Abdominal prostatectomy, however, is not free from recurrence rate, six patients in this series having previously undergone abdominal prostatectomy. Too short a time has elapsed for an adequate statistical follow-up of the recurrence rate, but a clinical impression of the results of punch prostatectomy was obtained by sending for consecutive patients so that 100 attended for personal examination, the last patient having been operated on 12 months previously.

Of these 100 patients, 11 of whom were in their 80's, the urine was crystal-clear in 86, hazy in 11, and turbid in 3. Of the three patients with turbid urine one, aged 72, had undergone four previous bladder operations elsewhere for prostatic obstruction and bladder diverticulum, resulting in a suprapubic sinus and heavily infected urine. The sinus closed after punch prostatectomy. The second, aged 64, was admitted with a perforated duodenal ulcer and developed persistent urinary retention after operation. A severe urethritis complicated his catheter drainage and necessitated a suprapubic cystostomy. No aetiological factor was present in the third patient: he was symptom-free, with a nocturnal frequency of one. He stated that normally his urine was clear.

Nocturnal micturition was nil in 33 patients, once in 30 patients, twice in 25 patients, and more than twice in 12 patients. This latter group of 12 is composed as follows: 3 patients, two to three times; 4, three times; 2, three to four times; 2, four times; 1, six times.

One patient was aged 83 and 7 were in their 70's; 2 patients had malignant prostates; 3 had hypertension with systolic blood pressures of 250, 240, and 220 mm. Hg; 4 spent thirteen hours in bed, and many drank fluid during the night. One patient, a restless facile 79 whose nocturnal frequency was six, drank more than a quart of fluid during the night.

In this aged, or bad-risk, group the standard of judging post-operative results clearly differs from that obtaining in the fitter group. The former patients stay in bed longer, frequently drink fluid during the night, are more intolerant or restless, and show a high incidence of raised blood pressure, cerebral arteriosclerosis, myocarditis, and polyuria. For these patients to have survived operation with a good urinary stream must be judged a satisfactory result. Most of them would formerly have been considered unfit for prostatectomy and would have been treated by permanent suprapubic cystostomy.

Status of Punch Prostatectomy

Punch prostatectomy is no new surgical adventure. In the Mayo Clinic, where the operation is carried out in almost 100% of cases of prostatic obstruction, over 14,000 cases have been treated by punch prostatectomy since 1933. It can be safely said, therefore, that this operation has successfully withstood the tests of time and experience, so that the wave of enthusiasm that so often sweeps a new operation beyond its established limits has had time to recede.

The outstanding impression after 400 cases of punch prostatectomy is without question the greater safety of this operation as compared with abdominal prostatectomy. At least four patients successfully resected were so dyspnoeic that they could not lie flat either during or after the operation.

Case Record.—A patient, aged 80, was admitted in 1947 with prostatic dysuria and cystitis. The blood urea was normal;

symptoms improved on penicillin and sulphamezathine, and therefore operation was not advised. He was readmitted 12 months later with incapacitating symptoms and a rising blood urea: no improvement occurred on penicillin and sulphamezathine. Punch prostatectomy was carried out under low spinal analgesia without a suprapubic cystostomy when his blood urea was 120 mg. per 100 ml. Convalescence was satisfactory; his blood urea returned to normal.

Operation on the worst risks indisputably provides the best test of safety. If an operation is safer for bad risks it is also safer for good risks. Five factors contribute to this safety: the operation is carried out under one of the safest of anaesthetics—a low spinal; the operation can be terminated at any point of time dictated by the patient's condition; it is a closed prostatectomy; an abdominal operation with all its well-known sequelae can be avoided; and there is a smooth, rapid, and ambulatory convalescence. The day after operation an average poor risk is on light diet and usually walks some 30 to 60 yards in one or two stages. Punch prostatectomy has reduced to a minimum operative trauma and therefore the operative mortality rate.

Apart from the route of access, punch prostatectomy possesses at least two distinguishing features. First, as the prostate is removed in portions the operation time varies directly with the size of the prostate; secondly, it is a highly specialized procedure requiring a long period of training. Failure to realize the importance of these two points may lead to some disillusionment. The operation time must not exceed three-quarters to one hour: a surgeon with little experience of this work may remove some 15 to 20 g. in this time. If the prostate is large (80-100 g.) the patient will at this rate of resection require multiple operations for an adequate removal, and if he is fit enough to survive these multiple operations will certainly develop a severe cystitis or pyelonephritis. Experience with the operation, however, increases both the speed and the safety of resection. The largest weight of tissue I have resected, in an orderly fashion with due care and time for adequate haemostasis, is 84 g. in one hour. This brings the majority of cases of prostatic obstruction, in one or two stages, well within the range of transurethral surgery. It has been estimated that in only 7% of cases does the prostatic weight exceed 100 g.

The textbook indications for punch prostatectomy are for prostatic obstruction due to fibrous, malignant, and small adenomatous glands and for prostate obstruction in bad surgical risks. The weak point in this classification lies in its confusion of clinical with pathological types, as it is quite clear that bad surgical risks, to whatever age group they belong, often have not only fibrous, malignant, and small adenomatous prostates but large prostates as well. A bad surgical risk, a large or difficult prostate, and an inexperienced resectionist constitute a lethal combination. The old idea that normal micturition can be restored for any length of time, or even restored at all, by "guttering" the prostate or by removing a few grammes of obstructing tissue is, I believe, quite wrong. Removal of the middle lobe in a trilobed enlargement may allow the lateral lobes to fall together and perpetuate the obstruction, and a further incomplete removal of one lateral lobe allows the opposite lobe to swing over and the obstruction may still be inadequately relieved. The removal of prostatic tissue in these bad surgical risks with large prostates must be substantial but need not be subtotal.

The indications for punch prostatectomy are, I believe best given in terms of the size of the prostate and the experience of the surgeon; in other words, with great competence it is the operation of choice in the great majority of all cases of prostatic obstruction; with limited competence, some 15%. The occasional outside prostate should be

treated by abdominal prostatectomy. The status of the operation is therefore not a fixed one. Furthermore, any relative contraindication to abdominal surgery—i.e., obesity or a bad chest—constitutes an important indication for transurethral surgery. In this series 99% of all cases were treated by punch prostatectomy.

Discussion

Although punch prostatectomy has reduced mortality rates to a minimum, outstanding problems still clearly exist. Those that derive from a chronically distended bladder occupy a foremost place, the most serious being a bilateral pyelonephritis due to penicillin-resisting organisms superimposed on kidneys already damaged by prolonged back pressure.

With the outstanding exception of Wardill's work at Newcastle-upon-Tyne, the opinions expressed in this country on punch prostatectomy on the whole have either been unfavourable or have unjustifiably restricted the scope of the operation. This may well be due to technical inexperience. John L. Emmett, of the Mayo Clinic, in a most helpful personal letter in reply to the question of the number of operations at which a surgeon should assist before being allowed to carry out a punch prostatectomy himself, states: "This question is very difficult to answer for the reason that the manual dexterity of individuals differs so greatly. I think, however, that a man should have had experience in at least a couple of hundred cases before he can consider himself fairly well trained."

So far, little mention has been made of what to the patient is the most attractive feature of the procedure—namely, the absence of an abdominal operation. Elderly patients show a well-founded aversion to an abdominal operation, many in this series having at first refused prostatectomy on the assumption that it meant a "cutting" operation. The popular appeal of this operation is based on sound clinical experience. It is perhaps not out of place to emphasize the fact that bad-risk patients with mild dysuria and a low residual urine require a period of observation before operation is considered. Indications for operations in this group must be clear and beyond dispute.

Conclusion

The outstanding impression is the safety of punch prostatectomy and its freedom from post-operative incapacity. It is applicable to the majority of cases of prostatic obstruction. For the aged bad risk group it is in a class by itself.

In highly specialized work the surgeon is very much in the hands of his theatre and ward staff. In both these respects I have so far been particularly fortunate.

The Ministry of Health points out that patients in hospital for any length of time may accumulate substantial sums by way of benefit or pension from the Ministry of National Insurance or National Assistance Board. These sums, together with any cash handed over by the patient on admission, should be banked and a separate banking account maintained if necessary. A separate ledger account should be kept at the hospital for each patient who has money to his credit in this account and debited as cash or its equivalent is issued to the patient or purchases made on his behalf. Payments can also be made to relatives out of the account at the written request of the patient. In the case of mental patients for whom no officer has been appointed to act in accordance with paragraph 4 of H.M.C.(48)24, B.G.(48)22, a certificate should also be obtained from a medical officer that the patient understands the nature of the transaction. Any interest accrued to the patient's bank account may be placed to the credit of the committee's or board's endowment account for the benefit of patients' amenities generally. The accounts relating to these transactions should be under the control of the chief financial officer and should be submitted to the auditor.

OSTEITIS FIBROSA DISSEMINATA

BY

D. J. MacRAE, M.B., F.R.C.S.Ed.

Late Surgical Specialist, R.A.F.V.R.

Osteitis fibrosa disseminata is a regional fibrocystic disease of bone with distinct and characteristic features. Its aetiology is obscure. No familial or hereditary tendency has been noted (Lichtenstein, 1938), but its segmental distribution suggests that it may have its origin in a congenital abnormality (Adams *et al.*, 1940). The condition may be a sequela of icterus gravis neonatorum in which the liver fails to store and utilize vitamins (Braid, 1932, 1939). An embryological defect, with an associated endocrine condition (Albright, *et al.*, 1937), and an abnormality in the region of the hypothalamus or walls of the third ventricle (Shallard, 1940) are also postulated as causes. The common features of the disease, the bone changes, may be the response of bone marrow to various stimuli—inflammatory, neoplastic, metabolic, or simple mechanical (Freund and Meffert, 1936). Trauma is common in childhood, and perhaps is too often present in the patient's history to be only of accidental importance; yet the disease cannot be produced experimentally by trauma (Freund and Meffert). Local bone changes, starting in childhood from various centres in the same bone, may be due to osteoclastic absorption and hydropic degeneration of the fibrous bone marrow as a consequence of the augmentation of pressure due to impaired venous flow (Freund and Meffert).

Symptoms and Signs

The condition first makes itself evident in childhood or adolescence, usually by fracture or bony deformity, and no extraskkeletal changes may be found. Braid observed from birth an infant who showed typical bone changes at the age of 2 years, and a second child who had the first of a series of fractures at the age of 1½. Both these patients suffered from icterus gravis neonatorum, and Braid states that at the age of 2½ years her female patient showed enlargement of the breasts and had a menstrual period, which lasted nine days. McClune reported bone changes in a 1-year-old infant, who also had icterus gravis neonatorum, in whom menstruation began at the age of 3½ years, and who was sexually mature at 4. Cutaneous pigmentation was seen in all three patients. There is no difference in the frequency of the sex incidence of the disease (Adams *et al.*, 1940); but endocrine dysfunction occurs typically in the female, and Albright described a further seven patients, four of whom were females, with the syndrome of osteitis fibrosa disseminata, areas of pigmentation, and sexual and somatic precocity.

Sex abnormalities in males are usually absent, although one case is recorded in which there was atrophy of the testes without any changes in the secondary sex characteristics. The general health is not affected and pain is conspicuously absent.

The Bone Changes

The bone lesions are the cardinal and sometimes the only features, and are responsible for the deformities and fractures which may be the first sign of the condition. Any of the skeletal bones may show the disease, but it is commonest in the lower limbs, where the ilium, femur, and tibia are most often affected. Bowing of the extremities is well marked, as in patients reported by Braid (1932, 1939) and by Murray *et al.* (1946); and kyphosis and

anterior bowing of the sternum have been described by Braid.

Braid also noted that in her original patient the bone disease did not attack the epiphyses, and it has since been found that they are constantly and characteristically spared, but the diaphyses are involved to a variable degree. Typical of the disease, too, is its regional distribution in bone, some bones showing patchy decalcification and others being completely normal. Deformities may also occur in the skull in the form of bony swellings, as in the case recorded below, or there may be asymmetry of the face (Coleman, 1939); tallness, due to delayed union of bone, is described by Shallard. The cystic areas of the affected bone vary greatly in size and density, and spontaneous fracture usually takes place through the site of a large cyst. These cystic areas, states Coleman, are clean-cut and involve the medulla and cortex, in some regions expanding the shaft of the bone and everywhere entirely replacing the normal bony architecture, with areas of increased density either associated with the cysts or appearing as irregular speckling; the cortex may be eroded as thin as paper. Freund and Meffert state that the internal moulding and resorption, instead of leading to the formation of lamellar bone, produces fibrous bone marrow and fibrous, porotic, spongy bone. The cortex is thin and expanded, owing to the encroachment on its endosteal surface, the periosteum playing no part in the pathology.

Macroscopically, the marrow spaces are wide and are filled with a yellow, white, or grey fibrous tissue, and the cavities with fluid of gelatinous material, forming true cysts or merely spaces filled with fibrous tissue (Adams *et al.*, 1940). Microscopically, dense fibrous-tissue cells replace normal bone and form irregular trabeculation throughout; osteoid tissue is common and indicates bone regeneration, which is occurring simultaneously with bone destruction; the cystic cavities are lined with compact fibrous tissue, and nests of foam cells can be seen (Adams *et al.*, 1940). Conclusive diagnosis of the different forms of non-generalized osteodystrophy is not always possible, however, from examination of a few slides.

The skull often shows osseous defects. Marked thickening of the base of the skull is characteristic, while the vault has a finely granular appearance. Shallard (1940) states that hyperostosis is most evident at the base of the skull, and that the mastoid cells and accessory sinuses may be completely obliterated by dense bone. In the vault the bone changes resemble those of early Paget's disease, with its bony thickening, multiple areas of rarefaction, and preservation of the inner table. Cystic rarefaction of the occipital protuberance is described by Garlock (1938).

Other Changes

Cutaneous pigmentation is not always present, but it has been recorded in so many cases as to suggest that it has a common exciting factor with the bony pathology. It may occur anywhere in the body, including the scalp, where it may be missed at examination (Albright); if the skull is involved in the bony pathology its distribution may be bilateral. The serum calcium and blood phosphorus are normal, but the plasma phosphatase level may be raised. The blood count is normal. Urine calcium excretion is normal.

Prognosis and Treatment.—The prognosis is relatively favourable; but multiple fractures and skeletal deformity are prone to produce serious incapacity. It is generally slow, and the course is benign. Treatment is confined to preservation of function and, if necessary, to correction of deformities.

Case Report

The patient, a male cine-projectionist, aged 25, had spent five years in the R.A.F., the last 3½ years overseas. His only complaint was: "My mother states that the lump on the back of my head has increased in size."

He had been employed as an electrician during his Service career and was carrying out routine duties, which included P.T., drills, and parades, but no strenuous course or heavy lifting. During the whole of his Service years he had not had any illness other than occasional colds in the head and influenza.

Previous History.—The patient's mother writes: "The lump on his head first became apparent at the age of 10 years. The right side of the head, at the back, appeared to be developing faster than the left side. A bulge appeared a year or two later on the left side of the forehead. He had a bad fall downstairs when 4 years of age, and also in childhood had bronchitis, otherwise he was always healthy, with no aches or pains. When he returned recently after 3½ years overseas, the lump at the back of the head seemed to have gone further down and to have spread across the top of the back of his neck to the left side. I am definite that the lump was only on the right side before, and was about a quarter its present size and going only half-way down on to the neck." There is also a history of fracture of the right humerus at the age of 15, brought about by very slight trauma. The patient was sitting at a table with other children playing a game which involved placing the elbows on the table, crossing the arms, and pushing the apposed hands of their playmates. It was merely this light pressure, applied by a girl, which fractured his arm, and he remembers at the time being struck by the fact. At the hospital at which he was treated no mention was made of any other complication when the fracture was radiographed. The bone healed in six weeks, and he then continued with his work as a cine-projectionist. He has never suffered from headaches or from ear or eye trouble. He has one sister, who is alive and well, but no brothers; his father and mother are also alive and well. There is no similar trouble in any member of the family.

On examination the patient looked fit and well; height 5 ft. 8 in. (1.73 m.), tongue clean. The teeth, except the lower incisors, canines, and first premolars, were removed five years ago for caries. Nothing abnormal was found in heart, lungs, or genitalia. The left frontal region protruded forward, causing slight left exophthalmos. Protrusion was also present over the whole of the occipital bone to the size of half a melon, more pronounced on the right side. The tumours were hard to the touch. No abnormal swelling or deformity was seen in limbs.

Clinical Findings

A radiograph of the skull revealed a large fibrocystic tumour over the whole of the occipital bone (Fig. 1). Both parietal bones show areas of decalcification and the outer table is raised in places with blister formation, and in other areas there is hyperostosis. The frontal bones show spotty decalcification and there is a fibrocystic swelling in the left frontal bone, with

FIG. 1

distortion of the left frontal sinus. The sphenoidal sinus is almost completely occupied by a tumour mass, and the mastoid air cells are obliterated. The inner skull table is normal. Radiographs revealed fibrocystic disease of the shaft and lower end of the humerus, with some cyst formation and trabeculation (Fig. 2). The cortical bone is seen to be eroded, and is especially thin at the junction of the middle and lower thirds of the shaft, where the bone is slightly expanded. All other bones are normal.

FIG. 2.

Radiography of the abdomen disclosed considerable calcification of abdominal lymph glands. No renal calculi or gall-bladder calculi were seen; the dye test was normal. Vision is 6/6 in both eyes, and the hearing normal.

Blood Findings.—June 3, 1946: red cells, 5,880,000 per c.mm.; white cells, 8,600 per c.mm. (neutrophil polymorphs 76%, lymphocytes 18%, monocytes 6%). June 17: serum calcium, 12 mg. per 100 ml.; blood inorganic phosphorus, 1.3 mg. per 100 ml.; plasma alkaline phosphatase, 18 King-Armstrong units; blood cholesterol, 200 mg. per 100 ml. July 2: serum calcium, 12 mg. per 100 ml.; blood inorganic phosphorus, 3.8 mg. per 100 ml.; plasma alkaline phosphatase, 14 King-Armstrong units. (Rapid rise of inorganic phosphorus noted.) Aug. 9: serum calcium, 10 mg. per 100 ml.; blood inorganic phosphorus, 2.6 mg. per 100 ml.; plasma alkaline phosphatase, 6.75 King-Armstrong units. (All estimations checked owing to variation from previous readings.)

Urinary System.—June 3: reaction, alkaline; albumin, sugar, and protein (Bence-Jones method), nil. Aug. 9: blood urea, 32 mg. per 100 ml.; urea

clearance, first hour 64% of normal, second hour 84% of normal (indicating only fairly good kidney function.) Urine calcium with known diet was within the range of normal. Faeces calcium, with known diet, also normal.

Discussion

Osteitis fibrosa disseminata has been described under a varied nomenclature, such as polyostotic fibrous dysplasia, osteodystrophia fibrosa unilateralis, osteitis fibrosa localisata, osteodystrophia fibrosa cystica generalisata, multifocal osteitis fibrosa, fibrous osteodystrophy, regional fibrocystic disease (Horwitz and Cantarow, 1939).

The possibility that icterus gravis neonatorum is a predisposing cause of osteitis fibrosa disseminata is suggested by Braid and elaborated by her in her record of two cases. McClune also reports this association. But whether the resulting bone changes are due to liver damage with consequent loss in vitamins, as Braid suggests, or whether the jaundice produces its effects elsewhere—as it does, for example, in the basal nuclei—are interesting speculations, as is the part played by haemolysis and anti-agglutinins on various organs. Braid states that Buchbinder and Kern produced rarefaction and cortical thinning and relatively wide medullary spaces and cysts in bones of puppies in which they had procured an obstructive jaundice; and they also brought evidence to show that there is some alteration in parathyroid function in obstructive jaundice. Braid, using the rabbit test in one of her patients, was, however, unable to demonstrate an excess of parathormone in the blood.

The blood changes in osteitis fibrosa disseminata frequently show a conspicuous alteration in the plasma phosphatase, which is often raised, while the blood calcium is

at the upper limit of normal. Periodic variation in the phosphatase level in the same patient, as reported by Braid, by Garlock (1938), and in the above case record, would also seem to be typical of this disease. Smith and Maizel state that a high plasma phosphatase is found in active rickets and is probably derived from hypertrophic cartilage cells and osteoblasts, which Robinson has shown to be the source of the enzyme, the phosphatase level slowly falling to normal with healing of the disease. They state that in scurvy, on the other hand, the plasma phosphatase is low, since the picture is one of cessation of bone growth and ossification is in abeyance—the phosphatase rising, however, with treatment of the condition and calcification of the haemorrhages, finally falling to normal with the absorption of these calcified areas. It could therefore be submitted that raised and normal plasma-phosphatase readings coincide with, and are respectively indicative of, active and quiescent phases of the disease.

The difficulty in distinguishing the disseminated form of osteitis fibrosa from the generalized osteitis fibrosa cystica of Recklinghausen is a very real one, and Shallard instances many patients in whom exploration of the neck proved negative. In Recklinghausen's disease there is an osteoporosis of the whole skeleton, with cyst and bone-tumour formation, a raised serum calcium, lowered blood phosphorus, a raised plasma phosphatase, and an excess of urine calcium, with possible stone formation and an association of the condition with an adenoma of the parathyroid gland. Non-typical cases of Recklinghausen's disease have also been reported; Weissenbach *et al.* (1939) state that parathyroid adenomata are not always present. Decort *et al.* (1942) found a hypocalcaemia, with normal, and later raised, readings for plasma phosphatase; and Marti (1938) records a case which was cured after the removal of a normal parathyroid. That the disease may become quiescent is recorded by Pagniez *et al.* (1938), and Ostling (1939) reports a spontaneous cure in another patient. Neither the blood chemistry nor the parathyroid changes would thus appear to be constant, and the condition may be quiescent at the time of examination. It is therefore essentially the extent of the bone changes and the age of the patient which are the diagnostic features. The fact that a raised blood calcium is not found in osteitis fibrosa disseminata, with its more localized bone changes, suggests that there is no adenoma of the parathyroid, and it may be surmised that the difference between the two conditions is that produced by minor or major disturbances of the parathyroid.

In both diseases there arises the question of the exciting factor of the abnormal parathyroid metabolism. That other endocrine glands can affect bone pathology is shown, for example, by the arrest of the bone changes in osteomalacia following removal of the ovaries; it may also be surmised that the temporary hormonal imbalance of the climacteric, which sometimes has a marked effect on the endocrines controlling carbohydrate metabolism, may also upset normal parathyroid activity and cause the bone changes found in Paget's disease. The anterior part of the pituitary gland is closely connected with normal growth of bone, and the association of Albright's syndrome with osteitis fibrosa disseminata points to this area as the seat of the trouble in this disease. There is no evidence about the cause of the parathyroid abnormality in Recklinghausen's disease—whether it is primary in the gland itself, as suggested by the cure which follows removal of the adenoma, or whether it is merely a more catastrophic alteration of parathormone balance in an older patient.

The skull changes in the case here reported have several points of interest. They form a prominent feature of the

disease and are more pronounced than those in cases previously recorded, and both base and vault are involved. The exophthalmos of the left eye is due to the frontal-bone growth displacing it forward; Albright described a similar instance. No involvement of the inner table of the skull is seen and the pituitary fossa appears to be normal. The cyst-like spaces and trabeculation and expansions of the occipital region and the "blister" appearance on the surface of the parietal bones show the results of an active phase of the disease. The hyperostosis in the vault is similar to that of early Paget's disease; while the solid replacement of the mastoid cells and the surface growth in the sphenoidal air sinus would seem to conform to the osteitis fibrosa of the creeping periostotic type of leontiasis ossium described by Lawford Knaggs. Had the disease in the present case involved the maxillary sinuses and, more typically, the facial bones, it might have been considered a definite example of leontiasis ossium. Cases of leontiasis ossium with involvement of other skeletal bones have been described ("Osteitis Fibrosa Generalisata as a Complication of Leontiasis Ossium and Coxa Vera": *Sei-I-Kai M.J.*, abstract section, Dec., 1936, 55, 1).

Finally, it may be thought that, instead of the fibrocystic diseases of bone being classified according to the region involved and the extent of the bone changes, many of them may be regarded as part of an abnormal parathyroid activity induced by alterations in the factors governing its metabolism and with trauma or vascular conditions playing a localizing part.

Summary

A case of osteitis fibrosa disseminata showing involvement of the skull and the right humerus and associated with certain blood changes is reported. It is suggested: (a) that the condition is one of endocrine abnormality in which the parathyroid hormone is dissociated from the normal endocrine balance; (b) that abnormality in the region of the pituitary or hypothalamus is the exciting cause and this may be due to haemolytic disease of the newborn; and (c) that the fibrocystic diseases of bone may be interrelated and their causal factors found in the different influences affecting parathyroid metabolism.

Previous history of icterus gravis neonatorum may be sought as a check made of the maternal history. Prolonged observation of the patient may reveal that the fibrocystic diseases of bone have periods of recrudescence and intermission.

I wish to thank Air Vice-Marshal Sir Andrew Grant, Director-General, Medical Services, for permission to publish the records of this case.

OCCUPATIONAL DISEASES OF THE LENS AND RETINA*

BY

JOSEPH MINTON, F.R.C.S.

Ophthalmic Surgeon to the Hampstead General Hospital, Queen Elizabeth's Hospital for Children, the West End Hospital for Nervous Diseases, and the London Jewish Hospital

This paper deals only with the diseases of the lens and retina that occur amongst glass and furnace workers, welders, and others exposed to excessive radiation at their work.

Radiant Energy and its Effects on the Eye

The visible rays occupy only a small portion of the radiation spectrum. The whole range of electro-magnetic radiation extends from the long electro-magnetic waves used in wireless and industrial high-voltage currents to the short gamma rays emitted from radium, uranium, and also during nuclear disintegration of atoms. Next to the electro-magnetic waves are the infra-red rays, which are generated by heated bodies (metal, glass, etc.) and are a source of danger to the eyes in foundries, glass factories, etc.

The long infra-red rays are mostly absorbed by the cornea. The short infra-red rays are transmitted through the cornea and are absorbed by the lens; a small part of these rays, however, reach the retina. The infra-red rays when absorbed by the tissues of the eye cause an increased activity in the tissue cells, and with it an overheating of the tissues. The cornea, which is air-cooled, suffers from no ill effects. The lens, on the other hand, when overheated through absorption of the short infra-red rays, undergoes marked changes, resulting in the formation of cataract. This form of "heat cataract" is found amongst glass-blowers, chain-makers, and foundry and furnace workers. The iris and ciliary body also absorb a good deal of the short infra-red rays; the heat generated in these tissues, however, is lost to the circulating aqueous.

The visible rays of the sun pass through all the media of the eye and on reaching the retina set up a series of biochemical changes which the brain interprets as vision. An excessive exposure of the eye to the sun rays may cause pathological changes in the eye.

The short and the long ultra-violet rays are absorbed by the cornea and the ocular conjunctiva, and only a very small amount of ultra-violet rays reaches the aqueous and the lens. The short ultra-violet rays set up biochemical changes in the conjunctiva and the cornea which manifest themselves "after a latent period" of several hours as a conjunctivitis or a keratitis. These ultra-violet rays are present in high quantities in welding arcs (gas and electric welding), and are responsible for the "arc eye" which is extremely common amongst welders.

The x rays and gamma rays are of very short wavelength; they penetrate the tissues of the eye and have a direct action on the lens, causing the formation of a cataract. Vascular changes are also set up in the iris and the ciliary body.

Occupational Eye Diseases due to Radiant Energy

In the past glass-workers have been known to develop cataract. In glass-bottle making the finisher was exposed to the undiminished glare of the furnace or tank of molten glass. The infra-red rays emitted by the molten glass were

*Abstract of Hunterian Lecture given to the Royal College of Surgeons in June, 1947. It was also read at the International Conference of Ophthalmology, London, 1947.

absorbed by the lens, and after many years the glass-workers developed typical "heat cataract." Investigations by Dr. Robinson and Sir Thomas Legge in 1908 showed that 20% of glass-workers had lens changes. These investigations have led the Government authorities to recognize "glass-blowers' cataract" as an occupational disease, and it is now scheduled as such under the British Workmen's Compensation Act, 1929. The recognition of this eye disease and the discovery that it is due to infra-red rays (heat rays), and not as previously thought to the ultra-violet rays, have led to further investigations into the means of its prevention.

Physicists found that glass to which metallic oxides are added can absorb about 90% of heat radiation. This glass, which is dark green, should be used in goggles and protective screens. Many glass-workers still use dark blue glasses which do not absorb a great deal of infra-red radiation.

Protection of the workers is best achieved by using machines which incorporate protective measures. This guiding principle inspired the inventors of the modern machines which are used in the making of glass bottles. The machine automatically sucks up the molten glass, blows the glass, and delivers the bottles at the rate of 40 a minute. The use of these machines is responsible for the great drop in the incidence of cataract amongst glass-workers. In Great Britain during the period 1939-45 only 27 cases of cataract were notified in the glass industry to the Ministry of Labour. In the year 1945 only one new case of cataract was notified. These figures were supplied to me by Dr. Merewether, Chief Medical Inspector of Factories in Great Britain, by the kind permission of the Ministry of Social Insurance. These figures should be compared with those of "glass-blowers' cataract" found by Dr. Robinson 40 years ago.

"Heat Cataract" in Metal Industries

Investigations carried out by ophthalmologists in many countries have now fully established the fact that workers in various metal industries, whose eyes are exposed to the heat from molten or red-hot metal, develop cataract. In Great Britain cataract caused by "exposure to rays from molten or red-hot metal" is now scheduled as an industrial disease.

In the years 1939-45 there were 131 compensation cases of cataract in the metal industry, while in the glass industry there were only 27 cases. In 1945 there were 16 cases of cataract in the metal industry, and only one case in the glass industry.

Evidently very little is being done in the metal industry to prevent the development of "heat cataract." I have visited several foundries in and around London, and have found that the eyes of the furnacemen and foundrymen were exposed to the heat of the molten metal. No eye protection was used by them. In some foundries electric furnaces are used, and the workers looking after these furnaces inspect the molten metal for very short periods only; but the furnacemen looking after gas-heated furnaces are exposed to the heat of the molten metal for many hours a day without any eye protection. Only through adoption of efficient means of protection of the workers' eyes will the number of cataract cases in metal industries diminish.

Chain-makers' Cataract

In Staffordshire there are about 1,200 people working at chain-making, hand forging of chains. In 1921 Dr. Roberts, ophthalmologist of that district, reported that "heat cataract" is common among chain-makers. Since that date a number of cases of "chain-makers'

cataract" have been reported by many other observers.

The workmen do not seek advice until their vision has become poor. At the age of 50 or over, by which time the chain-maker has been at his trade for some 35 years, lens changes typical of "heat cataract" often occur. It is interesting to note that the lens changes progress even if the chain-maker leaves his trade.

Dr. Lloyd Johnstone, ophthalmologist in Staffordshire, has seen 50 new cases of "chain-makers' cataract" during the past 10 years. The workmen are often advised to use dark glasses or goggles provided with "inflex glass" at their work, but they always claim that they cannot work with glasses, and it is very difficult to persuade them to do so while their sight is good.

Eye Hazards in Electric and Gas Welding

The most common types of welding used in industry are gas and electric welding. In gas welding oxygen or acetylene is used. Acetylene produces one of the hottest flames (6,000° F.—3,315° C.); oxygen welding reaches a temperature of 4,000° F. (2,204° C.).

All welders have at some time suffered from "arc eye," or "welders' flash." This condition is due to the exposure of the unprotected eye to the ultra-violet radiation of the arc in gas welding or electric welding. The welder is exposed to the radiation of his own work and to the reflected radiation from neighbouring workers. On examination one finds a conjunctivitis with an occasional superficial keratitis. The extent of the corneal involvement will depend on the length of the exposure to the arc and on the intensity of the radiation. The acute symptoms usually last one to two days. Repeated exposures to the arc produce a chronic blepharo-conjunctivitis with a chronic keratitis. The presence of the latter condition is often missed. A careful examination of the patient with a slit-lamp microscope will in such cases show the presence of multiple corneal erosions which stain with fluorescein.

The great heat generated by the welding arc is the source of intense infra-red radiation. Some of this radiation is absorbed by the eye and transformed into heat energy. Although most of this energy is absorbed by the cornea and conjunctiva, some of it (4 to 6%) may be absorbed by the lens. The lens cannot lose heat as easily as other parts of the eye and serious injury of the lens may follow.

Opinions are divided about the frequency of cataract among welders. However, many observers claim that lens opacities of the same type as have already been described occurring among furnacemen are to be found in elderly welders. Welders who may be suffering from some general disease or those whose state of nutrition is poor are liable to greater damage of the lens as a result of such physical factors as infra-red radiation. Eye injuries due to infra-red rays will go on occurring until better protective equipment is provided for the welders.

Retinal Injuries from Infra-red Radiation

Retinal injuries among welders are rare, but a number have been recorded. In these cases the central part of the retina shows definite changes. They may vary from a slight haziness of the macula to a pronounced oedema. The patients usually complain of a partial loss of vision, they may be aware of seeing a black spot in the centre of vision of one or both eyes, and their central vision may be very poor. Cases of mild oedema of the macula may fully recover; on the other hand, severe burns of the macula have led to a complete or partial loss of central vision. Ophthalmoscopic examination of the eyes many months after such an injury may show no macular changes, or a slight granular

appearance of the macula may be seen. In severe cases a "retinal hole" may be found at the macula.

I recently saw two men who were suffering from retinal burns from the welding arc. These patients were shown at the Congress of the Ophthalmological Society of the United Kingdom in March, 1947. Dr. White's patient was a fitter who was working 6 feet (1.83 metres) away from the welding arc. He had no eye protection when the arc was struck. A few days later he complained of blurred vision of one eye. He was seen a few weeks after the accident, and he then had a typical oedema of the macula, which later subsided. I saw him several months after the accident, and he then had an excavation (a hole) at the macula of one eye. The other patient, shown by Dr. Spence Meighan, was a welder. He attended at the Glasgow Eye Infirmary on March 16, 1945. He then complained of blurred vision of the right eye. His eyes were exposed to a flash from electric welding three days earlier. He had an oedema of the right macula. The vision of the right eye was 6/9. The left retina was normal; vision was 6/5. The oedema of the right macula subsided within a few weeks. The vision improved to 6/6. He now shows a fine pigmented disturbance at the right macula, and he has a small absolute scotoma at the point of fixation.

The retinal burns described above are largely produced by infra-red radiation of the welding arc. Investigations on the transparency of the ocular media to the radiation of various wavelengths have shown that 12% of the infra-red radiation of the welding arc reaches the retina of the unprotected eye.

Eye Injuries due to High-voltage Electric Currents

Burns of the body by high-tension electric currents are known to be sometimes followed by the formation of cataract in one or both eyes. A number of such cataracts have been reported by ophthalmologists. Such injuries occur in high-power electric stations where electricity is either produced or distributed.

The rarer type of injury to the retina may occur when a workman's eyes are exposed to a sudden electric flash from a high-voltage electric current. The following two cases illustrate the salient points of "electric eye injuries"

Case 1

An electrical fitter aged 39 was working in a trench on Jan. 27, 1946, repairing switch gear in a transformer substation. The voltage of the electric current in this station was 6,600. As a result of a short-circuit he was severely burnt; he was pulled out from the trench in an unconscious state and was admitted to hospital, where he remained unconscious for six hours. He was suffering from severe burns of the right side of the face, the right side of the scalp, and the right arm. He was away from work for three months. A week after his return to work he noticed a slight mistiness of vision of the right eye. He was then examined at an eye hospital, where he was found to be suffering from lens opacities of the right eye.

I examined him for the first time in March, 1947, fourteen months after the accident, and found the following: *Right eye:* Vision 6/24. The cornea and iris were normal. The slit-lamp microscope showed a dense central opacity in the anterior lens capsule and the underlying lens cortex. The peripheral parts of the anterior lens surface showed faint opacities, as though a veil was spread over the lens surface. The posterior cortex of the lens showed early changes. *Left eye:* This was normal in all respects and the vision was 6/5.

I examined him again in October, 1947, and he then told me that since August the vision of the left eye was not as clear as it used to be. Slit-lamp microscope drawings were made of both eyes. The left lens showed hundreds of small opacities on the anterior surface of the lens. The optical section drawing showed these opacities to be confined to the anterior lens capsule. The vision of the left eye was still 6/6. The drawing

of the right eye showed that the central lens opacities had become much denser. The optical section drawing also showed a pronounced thickening of the central part of the anterior lens capsule.

The outstanding features of this case are: (1) The right lens developed "an electric flash" cataract three months after the injury. (2) The left lens remained clear for eighteen months and then, about twenty months after the injury, it began to show lens opacities. These will most probably increase and will eventually cause the loss of vision of this eye.

Similar cataracts have also been reported in people who were struck by lightning. The causation of the "electric cataract" has never been satisfactorily explained. It is most probably due to chemical changes in the ciliary body of the eye and the lens capsule during the passage of the high-tension electric current through the body.

"Electric flash cataract," as a result of an exposure of the workman's eye to a powerful electric flash, is rare, but a few cases have been reported in the past. Retinal injuries from electrical flashes are much more common. The following case illustrates this condition.

Case 2

A man aged 25 was working on Nov. 29, 1946, on a switch gear of an electric generator. A short-circuit in the switch gear caused a powerful electric flash. He suffered from no general ill effects; he was not burnt. Three days later his left eye was slightly red and painful and he could not see with it. He was examined four days after the exposure to the electric flash. The vision of the left eye was then reduced to perception of light. The cornea, iris, and lens were normal. The central part of the left retina was oedematous. There were no retinal haemorrhages or exudates. The right eye was normal and the vision of this eye was 6/5.

A few weeks after the accident the vision of the left eye began to improve and the retinal oedema gradually subsided. He was away from work for three months. One year after the accident the vision of the left eye was 6/9, the oedema of the left central retinal area had subsided, and the macula had a granular appearance with a few pigmented dots.

These retinal changes resulting from electric flashes have been attributed by various observers to the infra-red radiation and to the intense visible light rays. It is impossible to state which of those rays are primarily responsible for the damage to the retina. The intensity of the light from a short-circuit has been estimated to be equal to the light of 150,000 candles; it is therefore probable that the photo-chemical changes produced by this intense light play an important part in producing the retinal changes.

Industrial Uses of X Rays and Radioactive Substances

X rays are used nowadays in many industrial processes—for example, in the examination of metals, micas, rubber products, textiles, etc.

The recent research on atomic energy demands a vast expansion of the work of extracting uranium and other radioactive substances from minerals. Great care must be taken to protect these workers from the dangerous effects of radioactive substances. If such care is not taken we shall soon read reports about severe anaemias and cataract of the eyes among the workers in these industries.

The Ministry of Health has sent a circular to local authorities and medical officers of health pointing out that two short films—one on diphtheria immunization and the other on burning and scalding accidents to children—may be borrowed free from the National Screen Service, Wallace House, 113, Wardour Street, London, W.1, if a cinema manager will include them in his programmes. They have been sent out before, but in some cases have been cut from the newsreel for various reasons. When asking for the films, three weeks' notice should be given of the date when the cinema manager has agreed to show them. They will be sent direct to the cinema

FREQUENCY OF PENICILLIN-RESISTANT STAPHYLOCOCCI

BY

A. VOUREKA, M.D.

AND

W. HOWARD HUGHES, M.D.

(From the Wright-Fleming Institute of Microbiology, St. Mary's Hospital, London, W.2)

Because of the large number of strains which are now grossly resistant to penicillin statements have been made that the drug is losing its value in staphylococcal infections. There was reason to believe that the number of resistant strains had been exaggerated, so an investigation was undertaken to ascertain the sensitivity to penicillin of staphylococci taken at random from out-patients.

The patients were those attending our asthma clinic and they were not at that time suffering from obvious staphylococcal infections. There was no risk of cross-infection, as they were swabbed on their first attendance and came from widely separated areas of the country. The strains were collected between January and June, 1948.

Swabs were taken from the anterior nares and cultivated on blood agar from which a number of single colonies were selected from each positive swab. By the appearance of the colonies and by the presence or absence of haemolysis and of coagulase production, 315 distinct strains were selected from 241 patients. Of these, 191 were albus, 121 aureus, and 3 citreus. There were 185 coagulase-positive strains and 119 coagulase-negative (11 strains were not tested). All were tested for sensitivity by the ditch-plate method as originally described by Fleming and Allison (1922). The strains to be tested were streaked on either side of the ditch and compared with the standard Oxford strain planted at the same time. A strength of 10 units of penicillin per ml. was used in the ditch. After overnight incubation the zone of inhibition between the edge of the ditch and the edge of the growth was measured with callipers. The results obtained are shown in Table I.

TABLE I.—Resistance to Penicillin of Staphylococci Taken at Random

No. of Strains	Distance of Inhibition from Penicillin Ditch	Remarks
Standard Oxford strain	16 mm. (average of all plates)	Standard control
55 73 75	203 { 10 mm. Standard \pm 1 mm. " " \pm 2 mm. }	Regarded as the same as control
1 2 1	{ + 3 mm. + 4 mm. + 6 mm. }	More sensitive
29 30 16 3 4	{ - 3 mm. - 4 mm. - 5 mm. - 6 mm. - 7 mm. }	Less sensitive
26	" - over 7 mm.	Provisionally classed as resistant

Penicillinase Production

On these figures, 26 strains may be provisionally classed as resistant; 24 of these were tested for their power to produce penicillinase. The method employed was as follows:

The resistant strains were again planted on a ditch plate, similar to the one used before, with 10 units of penicillin per ml. of agar in the ditch. On each side of, and as close as possible to, the resistant strains streaks of the standard Oxford staphylococcus were planted. At some distance a similar streak of the standard Oxford staphylococcus was planted as a control. Whenever the resistant strains produced penicillinase the ditch end of the Oxford staphylococcus streak had

a slanted instead of a straight edge, with the protruding point nearer to the streak of the resistant staphylococcus. The streak was noticed to encroach on the zone of inhibition as incubation continued, creeping gradually nearer to the ditch.

It was thus found that 11 strains produced penicillinase and 13 did not.

Titration of Resistant Strains

Of these 26 apparently resistant strains, 16 grew to within 2 mm. of the ditch and were regarded as definitely resistant, but it was decided to see exactly what concentration of penicillin would be tolerated by the remaining 10 strains which showed zones of inhibition of from 3 to 8 mm. from the ditch. The 10 strains were subcultured a few weeks after isolation, but unfortunately one failed to grow.

In testing the surviving nine strains dilutions of penicillin in broth from 12.5 units per ml. to 0.02 unit per ml. were used. The amount of the inoculum was 100 c.mm. of a 24-hour broth culture to 5 ml. of broth. The results are given in Table II. These show that of the 26 strains pro-

TABLE II.—Titration of Partly Resistant Strains

Strain	Inhibition on Plate		Concentration Inhibiting (Units/ml.)	Concentration Not Inhibiting (Units/ml.)
	At Time of Isolation	At Time of Titration		
1	Standard - 11 mm.	No inhibition	Not inhibited by 12.5	—
2 and 3	" - 13 mm.	Standard - 13 mm.	12.5	6.25
4 and 5	" - 12 mm.	" - 13 mm.		
6	" - 9 mm.	" - 10 mm.	1.56	0.78
7	" - 8 mm.	" - 10 mm.		
8 and 9	" - 10 mm.	" - 8 mm.	0.78	0.39
	" - 10 mm.	" - 7 mm.	0.39	0.19
	" - 11 mm.	" - 1 mm.	0.09	0.045
	" - 13 mm.	" - 2 mm.	0.045	0.02
Standard staphylococcus				

visionally classed as resistant, one was sensitive to 0.5 unit per ml. and two to 1 unit. Two strains had recovered their sensitivity to penicillin and one had apparently become more resistant.

If we take resistance to 1 unit per ml. as our arbitrary standard of a "resistant" staphylococcus, we have only 24 resistant strains out of 315 (including the two strains which in a few weeks acquired sensitivity and the one which died out)—that is, 7.6%. These 24 strains had the following characters:

Colour			Coagulase Test		Not Tested
Aureus	Albus	Citreus	+	-	
12	11	1	14	7	3

The proportion of resistant strains appears to be independent of whether the strains are aureus or albus, or coagulase-positive or coagulase-negative.

Summary

In a survey of 315 distinct strains of staphylococci, only 7.6% were found to be resistant to 1 unit of penicillin.

Housing associations provide residential accommodation for old people, and, though receiving financial help from local authorities, they retain the character of voluntary organizations. The National Old People's Welfare Committee has issued a useful pamphlet called "Why Housing Associations?" on how to start them, what their scope is, and who can help those interested in them. It is obtainable from the National Council of Social Service, 26, Bedford Square, London, W.C.1, for 6d.

Medical Memorandum

Creeping Eruption and Intestinal Strongyloidiasis

It is felt that, following observations taken over a period of three years, enough evidence has been accumulated to warrant the publication of a preliminary note on what appears to be a hitherto undescribed association between infestation with *Strongyloides stercoralis* acquired in the Far East and the condition of creeping eruption (larva migrans).

Creeping eruption resulting from the exposure of the unprotected skin of man to mature filariform larvae of canine, feline, and human hookworms in moist shaded soil contaminated by the infected faeces of dogs, cats, or man is well recognized by such authorities as Becker and Obermayer (1947), Belding (1942), Craig and Faust (1945), Faust (1939), Manson-Bahr (1945), National Research Council (1945), Stitt (1942), and Stitt, Clough, and Branham (1948). In the vast majority of cases, however, the skin lesions have mainly affected the hands and feet; in one case the migrating larva was observed wandering over the hand for as long as twenty-four years.

Stitt (1942, p. 1521) states: "Sandground (1939) describes a personal experience of 55 days of irritation, often infuriating, which followed on the spilling on the finger of infected larvae of *A. braziliense* and of a *Strongyloides* species, both obtained from the faeces of the cat. There were intermissions followed by reappearance of symptoms. A piece of skin was cut. The epidermal tunnels were empty, but the larva was found coiled in the corium 1.5 mm. from the surface." The reader is left with the presumption that the larva was that of *A. braziliense*.

In January, 1946, during a routine clinical examination of a patient admitted to the tropical diseases unit of Queen Mary's Hospital, Roehampton, it was noted that he had a tortuous linear urticarial weal affecting his buttock, starting near the anus and extending upwards towards the iliac crest. It was intensely itchy and progressed at a rate which was later found to vary from two to four inches (5-10 cm. an hour). This rate of progress is much in excess of that of the hitherto described forms of creeping eruption, which vary from a fraction of an inch to several inches in twenty-four hours. The patient was an ex-prisoner-of-war from the Far East and had worked on the Burma-Siam railway. Investigation showed him to be suffering from both ankylostomiasis and strongyloidiasis, but despite the successful treatment of the ankylostomiasis the creeping eruption persisted, as also did the strongyloidiasis.

It was subsequently noted without exception in a series of several hundred cases that this type of creeping eruption—i.e., a tortuous or serpiginous linear urticarial weal—occurred only in ex-prisoners-of-war from the Far East, and that they had been held in captivity in grossly insanitary conditions in Burma and Siam, with one case from Java. Their blood picture showed an eosinophilia varying from 10 to 25%, with a total white cell count often within normal limits giving absolute eosinophil counts of 700 to 2,000 per c.mm.

Apart from less than 2% of all cases of creeping eruption in which no helminth ova or larvae could be found on repeated microscopy, including after emigration and by concentration methods, all the cases have been associated with the finding of larvae of *S. stercoralis* in the faeces. In cases in which there was multiple helminth infestation the creeping eruption has persisted to date despite the eradication of all helminths other than *S. stercoralis*.

Specimens of larvae obtained from the faeces of these cases submitted to Professor Buckley, D.Sc., professor of helminthology at the London School of Hygiene and Tropical Medicine, for his opinion have been shown by him to differ in no way from the type species *S. stercoralis* (Bavay, 1876). He did state, however, in a personal communication, that some of the larvae examined were rather more mature in the cases associated with creeping eruption. Professor Buckley attempted to infect

himself with fully matured larvae from one of these cases, but fortunately, in view of their resistance to treatment, the attempt was unsuccessful. The creeping eruption begins in most cases in close proximity to the anus; it may extend downwards, affecting the upper third of the thigh, but has never been observed below this. It also affects the buttocks and the posterior and lateral aspects of the body as far upwards as the shoulders, but has not extended into the arms beyond the axillary folds. Anteriorly it occurs over the lower half of the abdomen, not affecting the external genitalia, and in some few cases the anterior surface of the chest has shown the characteristic lesions. It causes considerable itching and irritation.

Definite proof of the causation of the creeping eruption by wandering larvae of *S. stercoralis* is still lacking, as owing to the rapid rate of progress of the linear urticarial weal and its tortuous course the removal of a sufficiently large area of skin to include the postulated larva would be unjustifiable. Presumptive proof is also lacking, as it has been impossible as yet to find any method of treatment which will eradicate the intestinal strongyloidiasis. Gentian violet, hexylresorcinol, antimonials such as sodium stibogluconate, lithium antimony thiomalate, and "hetrazan" (1-diethylcarbamyl-4-methyl piperazine hydrochloride) have all proved uniformly unsuccessful.

Fortunately the skin irritation has been found to be amenable to symptomatic treatment with the antihistamine group of drugs.

It is hoped at a later date to publish a description in full detail of this condition.

I am indebted to Dr. J. F. E. Prideaux, C.B.E., Director-General of Medical Services, Ministry of Pensions, for kind permission to publish this memorandum. I would also like to make due acknowledgment of the very considerable help I have received from Dr. R. A. Gordon Smith, whose careful case histories and clinical examination played no small part in the establishment of this clinical association; to Drs. Mackenzie Douglas and C. C. Chesterman for much helpful advice; and to Professor Buckley for the kind interest he has shown and for his work on the morphological details.

The Ministry of National Insurance states that every employee is responsible for telling his employer of any accident he may suffer at work. This is one of the provisions of regulations made under the Industrial Injuries Act. The employee's notification to the employer may be oral or in writing. To facilitate this part of the procedure certain employers are required to keep readily accessible an accident book in which, if the employee chooses, he may enter the particulars required by the regulations. These are his full name, address, and occupation; date and time of the accident; the place where it happened; the cause and nature of the injury; and the name, address, and occupation of the person giving notice if it is not the injured person. The obligation to keep an accident book applies to every employer who normally employs, at the same time, ten or more people on or about the same premises in connexion with a trade or business, as well as to every owner or occupier, who is an employer, of any mine or quarry or of any premises subject to the Factories Act, 1937. If an accident occurs an employer is also responsible for investigating the circumstances of it and for noting any discrepancies in the facts. If the employee makes a claim under the Industrial Injuries Act the employer will be asked by the local National Insurance Office for a report on the circumstances as found by him.

Reviews

SPEECH THERAPY

Twentieth Century Speech and Voice Correction. Edited by Emil Froeschels, M.D. (Pp. 321. No price given.) New York: Philosophical Library.

In spite of its somewhat popular title and startling binding in scarlet and blue this book contains much sound and scientific matter of considerable interest to the neurologist, psychiatrist, and speech therapist. Eighteen contributors have written sections in addition to Dr. Froeschels.

The first chapter is on the anatomy and physiology of the vocal apparatus and also the development of speech in the child, but the author does not describe the central mechanisms of speech. With regard to aphasia, he maintains that the "speech-pathologist cannot agree with many psychologists that there is little or no cerebral localization of speech function, nor can he accept exact anatomical localization." In general, it seems that he should follow the lead of the psychologist in admitting that certain areas subserve certain linguistic functions more than others but that the entire brain is needed for normal speech activity. The suggested classification of aphasic manifestations is rather complicated but includes the more generally accepted forms; this section is presented mainly from the viewpoint of the speech therapist and contains sound practical advice on the treatment of the aphasic patient.

The chapter on absent or delayed development of speech, "alalia," as it is here termed, seems to be unduly involved and does not sufficiently emphasize the congenital mental deficiency (amentia) that is often found. For the condition of word or language deafness, which in Britain is often referred to as "congenital auditory imperception," the term "psychic deafness," used by Heller, has been adopted. This designation is somewhat misleading, for it might well include hysterical deafness—an objection that is admitted. The difficulties of diagnosis between the various forms of apparent deafness in children are well appreciated. Although there is no doubt that audiometry is the most exact method of determining hearing loss, its application to young children up to six or eight years old has not proved very satisfactory because of the degree of active mental co-operation required of the patient. The author of this section states that "to date there has been no approach other than a differential diagnosis" in cases of "psychic deafness" (or auditory imperception). She would be unaware that a fair amount of work continues to be done in Britain not only in differential diagnosis but also in therapy by those interested in the treatment of speech disorders.

Discussing the controversial question of the aetiology of stuttering or stammering, the writer rejects the theory of "handedness" and considers the condition to be a psychoneurosis. Other sections of the work include one on "dyslalia" and two especially useful chapters on (1) speech therapy in cases of cleft palate and (2) voice training after laryngectomy. While some chapters are eminently readable, others can be regarded as suitable only for reference.

C. WORSTER-DROUGHT.

OCCUPATIONAL THERAPY

Principles of Occupational Therapy. Edited by Helen S. Willard, B.A., O.T.R., and Clare S. Spackman, B.S., M.S.inEd., O.T.R., with 19 collaborators. (Pp. 416; 46 illustrations. 25s.) Philadelphia and London: J. B. Lippincott Company. 1948.

Occupational therapy is defined as any activity, mental or physical, medically prescribed and professionally guided to help a patient recover from disease or injury. It shortens convalescence and improves the degree of recovery through techniques (well described in this book) which attack inactivity and idleness on the part of the patient. The authors' description of the ideal organization of a hospital department of occupational therapy may well inspire physiotherapists in Great Britain to demand better accommodation and equipment and a more important place in the hospital hierarchy. They ably

advocate the need for medical men to give initial instructions and follow up the cases regularly during treatment to assess progress. Every therapist is taught that occupational therapy must be medically prescribed, but every doctor is not. How often does the physician or surgeon in this country, or in the U.S.A. for that matter, give detailed instructions, or even any instructions, to the occupational therapist? As well as the diagnosis, the views of the doctor responsible for the patient are necessary on matters such as the mental or temperamental characteristics of the patient, his special aptitudes or interests, and the duration and frequency of work to be undertaken. Those sections of the book on the treatment of special disabilities—mental illness, paediatric diseases, trauma, paralysis of various types, arthritis, blindness, and tuberculosis—will be of wide interest and help to physiotherapists. The variety of individual experience ably presented makes this volume a valuable contribution to the subject.

DONALD STEWART.

BERGEY'S MANUAL

Bergey's Manual of Determinative Bacteriology. By Robert S. Breed, E. G. D. Murray, and A. Parker Hitchens, assisted by Sixty Contributors. Sixth edition. (Pp. 1,529. £4 2s. 6d.) London: Baillière, Tindall and Cox. 1948.

The medical bacteriologist who finds himself discussing a problem of bacterial classification and nomenclature is soon likely to discover that the criteria which he regards as important may be very different from those considered valuable by his colleagues in allied sciences. For example, the clinical pathologist and the veterinary bacteriologist may think of coliform bacilli in terms of potential pathogenicity and may take the view that antigenic structure is the most promising criterion for classification; the water bacteriologist is interested in the organisms as an index of faecal pollution and prefers to define strains in terms of the most rapid and reliable biochemical test; the public health bacteriologist is concerned with both viewpoints and also with that of the dairy bacteriologist, whose problem may be the identification of coliform organisms in milk in relation to their sources and effects; and, further, there is the scientist who would classify the organisms on the evidence of genetic relation with other species. It is not surprising therefore that each of these workers is apt to disregard the broader aspects and to adopt a classification satisfactory for his own limited day-to-day problems. Be that as it may, it is clearly desirable that the name applied by one should be understood by all, that there should be agreement on methods of naming, and that a complete list of existing names should be available for consultation before new genus or species names are proposed. As a book of reference in these respects, *Bergey's Manual of Determinative Bacteriology* is unrivalled.

The last edition of the *Manual* appeared in 1939. The new edition is bulkier, and, since the text is rearranged in double columns, it contains much more material. The book is the work of the three editors, assisted by sixty expert contributors who have been responsible for individual sections. In general, the criteria used in classification are morphology, biochemical characters, and to some extent pathogenicity. A first reaction to some of the more formidable lists—for instance, the 148 species of *Pseudomonas*—is to ask whether all those species are really necessary, but further perusal reveals that some of them are pathogens of codfish and caterpillars, gladioli and Gila monsters, about which the medical bacteriologist can hardly pass judgment. Rather one must be grateful to the authors for their wisdom in consigning to appendices very many names of organisms appearing in the literature but rejected because they are identical with recognized species, or inadequately described, or no longer available for full study. The relegation of much larger numbers of names to the appendices is a welcome feature of the new edition. In one genus this results in the recognition of less than a quarter of the species appearing in the previous edition, and there is no doubt that drastic pruning of other sections on these lines would greatly increase the value of the book.

Few in Britain will quarrel with the main classification into families, and some of the generic changes, such as the disappearance of *Eberthella*, will be welcomed. Other genera,

from hospital to auxiliary hospital or convalescent depot. The mean stay in the E.M.S. hospitals was about 25% higher than in military hospitals. Analysis of the hospital records at home demonstrated that in about 1 of every 8 primary operations for hernia the original condition reappeared within 12 months, that the fatality rate for perforated peptic ulcer was about 6%, that gastric ulcer was about twice as apt to perforate as was duodenal, and that no less than 50% of cases of internal derangement of the knee were the result of football. There were striking and significant differences in respect of infestation by *P. capitis* among intakes of A.T.S. in different parts of the country. Scotland had much higher rates than England, while the rate in Northern Ireland (65% of the intakes in 1944) was indeed spectacular.

Among the causes of wastage in the Middle East during 1943-4 diseases of the ear, nose, and throat were outstanding. In Italy more than one-quarter of the men admitted to hospital for the treatment of disease were suffering from malaria or venereal disease. Battle casualties and accidental injuries made up one-quarter and one-tenth of the total man-day wastage respectively. The mean duration of stay in hospital and convalescent depot was about 3½ weeks for disease, 4 weeks for accidental injury, and 7 weeks for battle casualty. Psychiatric disorders were relatively far less common both in Iceland and the Faroes than in the United Kingdom. In one and the same theatre of war Indians and Africans were less liable to diphtheria and more liable to tuberculosis than troops of European stock. Canadians and New Zealanders were specially prone to infective hepatitis, Indians to malaria and to eye diseases, Africans to dysentery and pneumonia, and Europeans to diseases of the ear, nose, and throat. The case fatality of enteric fever, tuberculosis, and typhus was relatively high among the Africans, that of tuberculosis relatively high among the Indians. Cerebrospinal fever was less fatal among African than among United Kingdom troops.

An analysis of the figures relating to the initial stages of the assault upon Europe showed that trunk wounds caused more deaths than any other type of wound, that head and neck wounds, as would be expected, were relatively important causes of death, that under 1% of arm wounds proved fatal, that leg injuries or multiple wounds accounted for nearly two-thirds of the long-term hospital cases, that nearly 30% of the casualties evacuated had multiple wounds, that about 5% of the injured received more than four wounds, that 15% of single wounds involved bones, that 90% of all wounds were due to either shells, mortar bombs, or gunshot in equal proportion, that about 80% of gunshot wounds were single injuries, and that even in battle much of the treatment given by surgical units was for injuries not due to enemy action.

It is, of course, impossible to do more than attempt to attract the attention of as many as possible to this report, which deserves the careful study of those who recognize the value of the information disclosed by statistics in the shaping of policy and in the assessment of the results of therapeutic trial. That the work of the Army medical statistician in war was appreciated is shown by the fact

that at the end of the war this statistical mechanism was continued by the creation of the post of honorary consultant in Army medical statistics and by the absorption of a rump of the Directorate of Medical (Statistical) Research into the Directorate of Hygiene.

MORTALITY OF BLEEDING PEPTIC ULCER

The mortality of haematemesis and melaena from bleeding peptic ulcer has been a subject of interest and debate for many years. In the early part of this century the mortality was not excessive. The cases reported by Bulmer¹ for 1902 to 1917 showed a mortality of 7%. During this period there were many cases of acute ulcers in young women and the mortality was low. This type of ulcer became less frequent, and to-day not more than 5% of admissions for haematemesis occur in women under 40, compared with nearly 50% forty or so years ago. From 1920 to 1930 the decline of ulcer in young women was associated with a marked increase in chronic ulcer in men, and this, as Tidy² has shown, was reflected in the rise in national deaths from ulcer in men over 40. These changes in the sex and age distribution of acute and chronic ulcers probably accounted for the much higher mortality from haematemesis from bleeding peptic ulcer reported in this country in the nineteen-thirties. Most hospital figures^{3,7} then showed a fatality rate ranging from 13% to 25%. It seemed probable that the institution of liberal feeding by Meulengracht^{8,9} in 1935 and the large blood transfusions introduced at the same time by Marriott and Kekwick¹⁰ would greatly improve the prognosis. This hope was substantiated by many short series of cases published in support of liberal feeding and by the experience of Meulengracht in Denmark.

Geographical differences of ulcer distribution make it difficult to compare series from different countries, and it is safer to study figures from one country only. Two comprehensive investigations in Britain have, indeed, recently shown a substantial decrease in mortality from bleeding ulcer. Smith¹¹ in 1945 reported a 6% mortality among 180 cases treated in Glasgow, and Avery Jones¹² two years ago reported 8% of deaths among 615 cases treated in a district hospital in North-west London. Unfortunately, three further series show that there has not been a uniform fall in mortality. For example, Baker¹³ reported 576 cases with 77 deaths (13.4%) over a six-year period, 1940-5, from Birmingham. Tanner¹⁴ had 62 deaths (10.5%) among 586 admissions to a South London hospital between 1941 and 1948. In this issue Lewin and Truelove present a valuable analysis of 305 cases of bleeding peptic ulcer admitted to the Radcliffe Infirmary as emergencies during the period 1938-47, with 58 (19%) deaths.

It is difficult to compare different series, and the many fallacies have been discussed by Avery Jones. It is noteworthy that in the three recent series^{11 12 13} with the lowest mortality the cases were under the continuous care of those who recorded the results of treatment. But the more important consideration must be the age distribution of the series. Lewin and Truelove demonstrate very clearly the great increase in mortality with advancing years, the fatality rate of the over-fifties being about five times as great as that of the under-fifties. Over the age of 60 the risk of haemorrhage increases greatly, as might be expected. Lewin and Truelove found that, contrary to general belief, a previous episode of bleeding does not increase the fatality rate. They were also unable to show that a long history of ulcer symptoms heightens the risk, which is correlated with the age of the patient.

In a comparison of different series, particularly when assessing therapy, it is essential to allow for varying age distribution. Thus, the low mortality of Smith's cases cannot, without further analysis, support his arguments against transfusion. In his series 12% of patients were over 60, compared with 29% in the Oxford series. The high mortality from Birmingham and Oxford leaves no grounds for complacency with medical treatment, and more information is urgently needed on modern experience with surgery for this emergency. Avery Jones's experience showed that the mortality was particularly high among patients over middle age with chronic ulcer and who had recurrent haemorrhage after admission to hospital: in this group there was a mortality of over 50% under medical treatment, and here there should be opportunity for surgery.

Cases may be conveniently classified on admission into two groups. First are those with probable chronic ulcer; they should have a history of recurrent dyspepsia of moderate severity, with recent pain for at least three weeks and, possibly, with previous x-ray or other evidence of ulcer. Approximately two-thirds of these cases have no further haemorrhage after admission to hospital, but some may need subsequent elective surgery. The remaining one-third will have brisk recurrent haemorrhage; it is in this group particularly that surgery may prove of the greatest value for patients over 45. The second main group are those with an acute lesion. Though they may have had a long history of dyspepsia it has usually been slight, and there has seldom been pain for more than two weeks; indeed, pain has often been absent. About three-quarters of these cases have no subsequent bleeding after admission, but the remaining quarter may bleed briskly and repeatedly. Nevertheless, with adequate transfusion the mortality remains low, and it is improbable that surgery has much to offer other than the exclusion of a rare diagnosis such as leiomyoma. Lewin and Truelove use a similar grouping for their series, and for assessing the role of surgery the probable clinical diagnosis on admission would be of greater value to others than results based on the final diagnosis. Sporadic surgery for haematemesis tends to be disappointing, as operation has often been reserved for patients with protracted bleeding. The present need is for the results of surgery based on a clear-cut policy with well-organized arrangements for co-operation between the physicians and surgeons. The recent experience of

Tanner¹⁴ is most encouraging, but his surgical data need presenting in greater detail. In view of the high proportion of cases over 60 (38%) his fatality rate of 10.5% for the whole series is not excessive. His last 60 admissions include 35 subjected to emergency operation, with only two deaths.

PUBLIC HEALTH SALARIES

At a time when remuneration of general practitioners, consultants, and specialists has been the subject of much controversy, discussion, and negotiation, the B.M.A. has not overlooked the salaries of that important group of medical men and women employed whole-time in the public health service. There has been considerable delay in tackling this problem because of the attitude of the Associations of Local Authorities. For some months now efforts have been made to begin through the Whitley machinery a much-needed review of the situation. At the meeting of the Council on Jan. 12¹ the Council decided to inform the Minister of Health of "the serious unrest and dissatisfaction among members of the public health service occasioned by the continued delay in opening negotiations on the new scales and conditions of service." The Council also decided that if by Feb. 28 negotiations had not begun through the Whitley machinery advertisements from local authorities would not be accepted by this *Journal* unless the salaries in the public health service conformed with the Association's proposals for the new scales. These new scales were given in the *Supplement* of Jan. 29. It should be emphasized that the new scales included a betterment factor of 20%. But this factor has not been accepted by the Association, and when negotiations are started it will be related to the betterment factor for other sections of the profession now being discussed with the Ministry of Health.

The present dispute is concerned only with the salaries of those employed whole-time in the public health service, who are now remunerated according to the terms laid down in the Askwith Memorandum. For example, under the Askwith scale the highest minimum salary that a medical officer of health in an area with a population of 100,000 can earn is £1,300, and the scale does not fix annual increments or a maximum salary. Under the Association's provisional proposal (provisional because the betterment factor of 20% is not accepted) the minimum salary would be £1,920, with annual increments of £120 up to the maximum salary of £2,400. The Associations of Local Authorities no doubt fear that if the salaries of their whole-time medical officers are increased they will have to face similar demands from other professional groups employed by them. The medical profession will not, however, accept this as an excuse for underpayment of medical officers. Nor can there be any sound reason for refusal on the part of the Associations of Local Authorities to open negotiations through the Whitley machinery, especially as this course of action is approved by the Ministry of Health. Until these negotiations are opened advertisements for vacancies in the public health service will be refused by the *Journal*, and in this we have the co-operation of the *Lancet*, *Public*

¹ *British Medical Journal Supplement*, 1949, 1, 34.

Health, and the *Medical Officer*, which have agreed on a similar line of action.

No one has yet computed the economic benefits to this country which have resulted over the past 100 years from the activities in the finest public health service in the world of men and women who have worked for a small enough financial reward. It is but bare justice that their modest claims should be met—and met promptly.

THE INHERITANCE OF ACHONDROPLASIA

The work of the Institute of Human Genetics of the University of Copenhagen was described in this *Journal* a few months ago.¹ Most of the monographs published by the Institute appeared during the war and so did not become known in this country until it was over. In a recent annotation² we discussed Andreassen's monograph on haemophilia in Denmark, and in the present annotation the third volume of the series, a study of chondrodystrophic dwarfs in Denmark by E. Trier Mörch,³ is reviewed. As in the study on haemophilia, an attempt was made to trace and examine every living achondroplastic dwarf in Denmark: 86 were found, and it is believed that the survey was in all probability complete or almost complete. In addition information was obtained about 22 recently dead subjects. The main purpose of the work was to elucidate the genetics of the condition, but there is much of clinical and general interest also, and the literature has been carefully surveyed; 442 references are given. The author has made use of historical records, and a number of famous portraits are reproduced. He describes achondroplasia in other animals and gives a full clinical and pathological description of the condition in man. In the course of the survey many deformed persons who turned out not to be achondroplastic dwarfs were brought to the author; the result is a particularly useful chapter on differential diagnosis. A review of the literature showed that while conception and pregnancy in the achondroplastic woman are normal the chances of obtaining a living child following vaginal delivery are very small and the risks to the mother are considerable; cesarean section, however, gives good results.

It had previously been assumed by a number of writers that the condition was due to a dominant gene with a high mutation rate, giving a considerable proportion of sporadic cases. Until the completion of Mörch's work, however, this opinion did not rest on very sure foundations and was indeed denied by some. Mörch comes to the clear conclusion that there is a very high mutation rate—1 in 10,000 in terms of individuals, or 1 in 20,000 in terms of chromosomes. He also concludes from maternity hospital records that 80% of the affected children die during the first year of life. If they survive this period their expectation of life is not abnormally short, though their reproductive rate is less than that of normal individuals. The consequence is that the majority of achondroplastic dwarfs are the result of a mutation in one or other parent and so are the first to be affected in their family group. Of the 108 dwarfs studied there were 90 sporadic cases and 18, belonging to eight sibships, in which the gene had been received from a similarly affected parent. There was no instance of transmission through more than two generations, though transmission through three and even four has been occasionally reported.

There are two important tests that must be applied before sporadic cases can be accepted as due to mutation. Such

persons, when they in turn have children, must, if the gene is dominant, have affected and normal children in equal proportions. In glioma of the retina, for instance, this requirement is not in all probability fulfilled; but the sporadic chondrodystrophic dwarfs in Mörch's series have had 10 affected and 17 normal children—sufficiently close to the expected ratio. The second test is that sporadic cases if due to mutation must not have any greater proportion of more distant relatives affected than ordinary normal people selected at random. If they have, this would point to occasional manifestation and the skipping of generations rather than to mutation. Again the Danish material passes the test; Mörch could not find a single affected individual among the more distant relatives of any sporadic case. There was one curious finding: the average age of the parents of sporadically occurring dwarfs was significantly higher than in the population generally. Mörch attributes this to a rise in mutation rate with age. This may well be so, but until similar findings are reported in other conditions the association with parental age should probably be regarded as somewhat weakening the evidence. Nevertheless this fine study makes the inheritance of achondroplasia sufficiently clear to enable the clinician to give unequivocal advice to patients. There is a 50% chance that any child of an achondroplastic dwarf, man or woman, with or without a family history of the condition, will be similarly affected. A normal couple who have had an achondroplastic child can be assured that the chance that a subsequent child will be affected is no greater than the 1 in 10,000 or so of any random normal pregnancy.

MODE OF ACTION OF INSULIN

Some metabolic processes are precisely adjusted by the action of hormones, and in a recent review of the mechanism of action of insulin Professor F. G. Young¹ has shown that the two key processes are the enhancement of the activity of liver phosphorylase and of hexokinase. The former of these enzymes catalyses the reaction in which glucose-1-phosphate is converted to hepatic glycogen. This reaction appears to take place when the blood sugar is raised, and, provided the blood sugar is not allowed to fall below the "liver threshold" of 90–110 mg. per 100 ml, insulin promotes the formation of hepatic glycogen. Glycogen then becomes available in the liver for the supply of glucose to the heart and brain or of glycogen to the muscles when required. The action of insulin on the hexokinase system is perhaps even more important. Preliminary phosphorylation to glucose-6-phosphate is necessary before glucose can enter the metabolic cycle. The reaction requires the addition of free energy and is catalysed by hexokinase. Cori and his colleagues² have shown that *in vitro* activity of hexokinase is inhibited by certain unstable pituitary extracts or extracts of the adrenal cortex. This influence is counteracted by insulin. Furthermore, insulin does not increase the activity of hexokinase derived from normal animals, though it does increase that of hexokinase derived from diabetic animals. The balancing mechanism is therefore a delicate one. The extreme "sensitivity" to insulin of the patient with hypopituitarism or of the diabetic with Addison's disease is not explained by this effect. Young suggests that in the case of the hypophysectomized animal the readily produced insulin hypoglycaemia may be due to enhancement of the phosphorylase mechanism.

Some authorities do not consider that insulin stimulates the oxidation of glucose directly. Nevertheless it is

¹ *British Medical Journal*, 1948, 1, 651.

² *Ibid.*, 1948, 1, 697.

³ *Opera ex Domo Biologiae Hereditariae Humanae Universitatis Hafniensis*, Vol. 3. Copenhagen, Ejnar Munksgaard, 1941.

³ *J. Amer. med. Ass.*, 1946, 132, 373.

probable that the hexokinase mechanism facilitates oxidation indirectly, the glucose-6-phosphate undergoing conversion to pyruvic acid, which is oxidized in the tricarboxylic acid cycle of Krebs. Another important effect indirectly produced by insulin is the abolition of ketosis. Recent evidence suggests that fatty acids are broken down by oxidative fission into two-carbon atom fragments, which may undergo oxidation in the liver or, failing this, condensation to the ketone, acetoacetic acid. To a lesser extent this ketone can be produced by oxidation of four-carbon fragments of the fatty acid, and either the two-carbon fragments or acetoacetic acid can be incorporated in the tricarboxylic acid cycle and oxidized. The initiation of this cycle depends on the utilization of carbohydrate. Failure to bring about oxidation of fat derivatives in this way and the absence of carbohydrate utilization in the muscles are necessarily followed by increased combustion of ketone bodies. This combustion in the muscles can apparently take place only in the presence of large quantities of blood ketone, and this accounts for the severe ketosis. It has long been suspected that insulin catalyses the conversion of glucose to fat, and Stetten² has proved this by the use of the isotope technique. Young shows clearly that this is quite in harmony with the well-known rise in the respiratory quotient that occurs after the administration of insulin to a diabetic.

OSTEOID OSTEOMA

Osteoid osteoma was first described as a clinical entity by Jaffe¹ in 1935; previously lesions which would now be recognized as osteoid osteoma had been reported under other names. The disease attacks males more frequently than females, the ratio being greater than two to one. It occurs mainly in adolescents and young adults, though the youngest patient on record was 3 and the oldest 51. The bones chiefly affected are the tibia, femur, astragalus, humerus, and vertebrae. The commonest symptom is pain, which is vague and intermittent at first, but later increases in severity and is often present at night. Precisely localized tenderness and thickening are the most obvious physical findings, and occasionally an effusion may occur in the adjacent joint. When the spine is affected localized back pain, increased muscle spasm, and secondary scoliosis occur. There are no blood changes, and the patients are afebrile. Radiography reveals the lesion as a rounded area of reduced density surrounded by sclerotic bone, but the bone may be so sclerotic that the central area cannot be seen on the radiograph. Excision of the lesion produces permanent and complete relief. The nidus, when exposed by operation, consists of a brownish or greyish mass of vascular connective tissue. Microscopic examination of this material shows cellular fibrous tissue containing multinucleated giant cells, associated with many irregular trabeculae of osteoid tissue. This latter tissue is irregularly calcified. Reporting thirty cases of osteoid osteoma Sherman² makes the point that it is likely that the lesion heals spontaneously, because in patients over the age of 30 the disease has been reported on only eight occasions.

The aetiology of the condition is still in doubt. The argument for trauma is not convincing, since few patients give a definite history of injury. Brown and Ghormley,³ in fact, deny the existence of osteoid osteoma, regarding it as "chronic inflammatory tissue." Brailsford⁴ in 1942 presented several cases with radiographs which were similar to those of osteoid osteoma. *Staphylococcus albus* was cultured from three of these cases, and he regarded the lesions as chronic subperiosteal abscesses. Against the

infection theory it is argued that these patients have no fever, leucocytosis, or other systemic manifestation, and that the organisms which are grown from the lesions have in the main been contaminants; in five cases guinea-pigs were inoculated, with negative results. Wassermann, Kahn, and tuberculin tests have all proved to be negative. Jaffe considers the lesion to be a benign neoplasm, and the constancy of the pathological findings supports this view. Tissue typical of an osteoid osteoma is not encountered in proved abscesses. The condition is not related to any activity of the haematopoietic tissue. Osteoid osteomas are small; they rarely exceed one centimetre in diameter. There is no record of their occurrence in the scapula, clavicle, or cranium, and only once has an osteoid osteoma been reported in an epiphysis. The nature of this condition is still obscure, and no dogmatic statement can be made about its origin.

ACADEMIC SALARIES

New salary scales for professors, lecturers, and readers in medical schools and in dental schools were the subject of a written reply by Sir Stafford Cripps to questions which were put to him on Feb. 28 by Sir Ernest Graham-Little and Mr. Somerville Hastings. Both the University Grants Committee and the Committee of Vice-Chancellors and Principals have had under consideration the effect of the Spens Report on the Remuneration of Consultants and Specialists on the salaries of medical and dental staffs at the universities. Both committees have been seriously concerned about the effect on staffing and recruitment of the disparity between the present academic scales and the rates of remuneration proposed for consultants and specialists by the Spens Committee. The proposals they put forward have been accepted by the Chancellor of the Exchequer, and the University Grants Committee has therefore written to the Vice-Chancellors indicating the revised general limits of salaries in the medical and dental schools for which supplementary grants will be made in the current quinquennium. Determination of the salaries of individual members of the staff will continue to be entirely within the discretion of the universities, but provision will be made in the estimate for the financial year 1949-50 to allow of supplementary grants being made for the purpose of readjusting salaries within the proposed limits.

The revised salaries for full-time clinical posts, which are to be paid from a date not earlier than April of this year, are: professors, £2,250 to £2,750 a year; lecturers, £600 to maxima of £1,500 to £2,000 a year, or in the case of lecturers holding posts of special responsibility, such as a headship of independent departments, £2,500 a year; salaries for readers will be within the range of the maxima for lecturers. For full-time preclinical posts the revised salaries will be paid from a date not earlier than Oct. 1 of this year and will be: professors, £2,000 to £2,500 a year; lecturers, rising from £600 to maxima ranging from £1,200 to £1,800 a year; readers, salaries within the range of the maxima for lecturers. It will be for the universities to decide in borderline cases whether particular posts should be treated as clinical or preclinical: for example, the University Grants Committee would regard it as reasonable if certain posts in the departments of pathology and bacteriology were treated as clinical posts.

Professor H. P. Himsworth, M.D., F.R.C.P., will deliver the Oliver-Sharpey Lectures before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday and Thursday, March 15 and 17, at 5 p.m. His subject is "The Syndrome of Diabetes Mellitus."

THE Rh FACTOR

BY

ALEXANDER S. WIENER, M.D., F.A.C.P.

I was very interested in the review (*Journal*, Oct. 2, 1948, p. 650) of the excellent monograph *The Rh Blood Groups and their Clinical Effects*, by P. L. Mollison, A. E. Mourant, and R. R. Race, as I had just completed reading that publication myself. This fine outline of the present status of the rhesus blood factors is clearly written and gives much useful information. However, it contains a number of errors of omission and commission, and the purpose of this paper is to point them out in view of any further editions that may be planned.

In Chapter I, which deals with the heredity of the Rh-Hr blood types, the discussion is unfortunately limited practically exclusively to the linkage theory sponsored by Fisher and Race, while the theory of multiple alleles sponsored by me is hardly mentioned at all. When discussing the linkage theory, moreover, the writers fail to point out that this theory, which is usually ascribed to Fisher, was actually first discussed by me in 1942. I found that the distribution of the Rh types differed markedly from the equilibrium values to be expected if heredity is determined by distinct pairs of Rh-Hr genes, either linked or independent, rather than by a simple series of allelic genes. (These calculations have recently been confirmed and extended by Rife.) Therefore I discarded the theory of linked genes in favour of the theory of multiple alleles. The monograph, too, fails to mention that the theory of multiple alleles is supported by the studies of myself and my collaborators, as well as those of Chown and Race himself, on families comprising more than 2,000 children. The theory is also supported by statistical studies on the distribution of the Rh types in the general population, as calculated with the aid of the following formulae (not including the rare genes r^0 and R^2) published by me in 1944:

$$r = \sqrt{rh} \quad (1)$$

$$r' = \sqrt{rh' + rh} - \sqrt{rh} \quad (2)$$

$$r'' = \sqrt{rh'' + rh} - \sqrt{rh} \quad (3)$$

$$R^0 = \sqrt{Rh_0 + rh} - \sqrt{rh} \quad (4)$$

$$R^1 = \sqrt{Rh_1 + rh' + Rh_0 + rh} - \sqrt{Rh_0 + rh} - \sqrt{rh' + rh} + \sqrt{rh} \quad (5)$$

$$R^2 = \sqrt{Rh_2 + rh'' + Rh_0 + rh} - \sqrt{Rh_0 + rh} - \sqrt{rh'' + rh} + \sqrt{rh} \quad (6)$$

theory of multiple alleles receives support from the fact the sum of the gene frequencies calculated with the aid of these formulae closely approximates to 100%.

One of the main objections to the linkage theory is its use as a basis for an elaborate and unnecessary duplicate system of nomenclature for the Rh-Hr types. Thus the linkage theory sponsored by Fisher and Race, for which there is no substantial evidence, in contrast to the theory of multiple alleles, not only is not original with these workers but has caused them to introduce a cumbersome system of notations which has served only to confuse the subject. For example, the following formulae for "chromosome" frequencies are given by Race in the monograph, being attributed to Fisher as of 1946:

$$cde = \sqrt{(-+---)} \quad (7)$$

$$Cde = \sqrt{(-+---) + (+-+--)} - \sqrt{(-+---)} \quad (8)$$

$$cdE = \sqrt{(-+---) + (-++-)} - \sqrt{(-+---)} \quad (9)$$

These formulae resemble closely formulae (1) to (6) given above, though expressed in less comprehensible hieroglyphics. Another disadvantage of this nomenclature, which Race himself admits on page 10, is that the C-D-E notations are "somewhat cumbersome to use in speech." The advantages of the simple name "type rh" for triple Rh-negative blood as compared with the designations used by Race—namely, "group -+---" and sometimes "group ---+"—are too

patent to require discussion. In Race's notations it is absolutely essential to specify the arrangements of the antisera, since four symbols can be arranged in as many as 24 different ways. Therefore Race has to resort to the use of the "short-hand" symbols R_1 , R_2 , r , etc., which are merely an adaptation of my original Rh-Hr notations. Thus those who insist on using the C-D-E notations are compelled to be familiar with two nomenclatures, while those who use the Rh-Hr notations get along very well with one. Moreover, in Table III Race himself finds that the Fisher-Race method of guessing genotypes entails errors as large as 49%, while I have shown that my own notations for the Rh-Hr phenotypes and genotypes avoid any error.

The monograph quite properly gives full credit to Levine and his collaborators for their pioneer work in demonstrating the role of iso-immunization to the Rh factor in the pathogenesis of erythroblastosis. It should have been mentioned, however, that the phenomenon of iso-immunization in pregnancy had been demonstrated previously by Jonsson in 1936 in the case of the A and B factors. Moreover, the concept of iso-immunization in relation to the pathogenesis of erythroblastosis was first advanced by Darrow in 1938, but this worker thought that foetal haemoglobin was the antigen responsible. Levine correctly demonstrated that Rh was the antigen usually at fault, but incorrectly ascribed the effect to Rh agglutinins. Following the independent discovery by myself and Race of the Rh blocking antibody, I demonstrated that blocking antibodies readily traverse the placental barrier, while agglutinins are effectively held back by the intact placenta, so that the blocking antibodies, or as they are also known the glutinins, are the real culprits in producing the disease, not the agglutinins.

When discussing exchange transfusion the excellent umbilical catheter method of Diamond is described in detail, but the saphenous-vein-radial-artery method of Wiener and Wexler is completely ignored even though this was proposed earlier and has been widely used with great success. The umbilical-catheter method has a popular attraction because of its seeming simplicity. However, there have been technical failures with this method even in the hands of experts, who then had to resort to the radial-artery method, which can always be used regardless of the age of the baby. Moreover, while there has been no operative mortality ascribable to the radial-artery technique, there have been occasional deaths following the blind umbilical-catheter method, due not only to air embolism but also to thrombosis and even haemorrhage into the abdominal cavity. In the monograph no mention is made of the fact that, regardless of the method used, one must take care to avoid the possibility of serious shock or even death from hypocalcaemia, which may be induced by the relatively rapid introduction of large amounts of citrate, especially when massive exchange transfusions are done. This complication can easily be avoided by repeated careful injection of 10% calcium gluconate in doses of 1 ml. each time 100 ml. of blood is administered to the infant.

In the section dealing with the difference between properties of behaviour of univalent and of bivalent antibodies it is rather surprising to find no mention made of my concepts of agglutination and conglutination. Moreover, there is no reference to my work proving that univalent antibodies pass through the placenta easily while bivalent antibodies do not—an observation of considerable importance not only for the pathogenesis of erythroblastosis but also for immunology in general. The term "albumin agglutinin" does not seem satisfactory, because it is based on a purely artificial though ingenious *in vitro* test with no counterpart *in vivo*. If the term "albumin agglutinin" is to be considered acceptable then why not "acacia agglutinin" or "plasma agglutinin" or "anti-human globulin agglutinin"? The terms "glutinin" and "univalent antibody" are free from such objections. As I have demonstrated, the univalent antibodies, after passing through the placenta, coat the foetal red cells, and clumping occurs only in the presence of a third component, conglutinin, found in normal plasma. Conglutinin has been shown to be a colloidal aggregate of plasma proteins which is related to or identical with X protein, and is analogous in many respects to complement. As shown by me and confirmed by Witebsky, the plasma of the foetus *in utero* is deficient in

conglutinin, which, however, matures rather rapidly after birth, thus accounting for the frequently delayed onset of signs and symptoms of the disease. Indeed, the main purpose of exchange transfusion is to remove the baby's coated red cells before they can clump by intravascular conglutination in order to avoid irreversible organic damage which could result from blockage of the circulation. Molison's statement on page 34 that icterus gravis is probably due indirectly to the primary damage to the baby's red cells is a partial admission of the correctness of these views, and at least does not subscribe to the theory held by many workers that the antibodies act directly on the tissue cells, which were supposed to possess Rh antigen.

With regard to the question of nomenclature it is especially important to review the evidence available at once, because the recent U.S. Government ruling that the C-D-E notations must be included in parentheses after the standard Rh-Hr notations when labelling antisera has forcibly brought the newer notations to the attention of technicians who had been perfectly content with the original, simpler notations. If the C-D-E protagonists have any real evidence in support of the linkage theory now is the time to present it if they sincerely believe that they are on the right side.

In this connexion the rather extensively cited single exception to the multiple-allele theory found by Glass is merely an illegitimate child, and at any rate, observations on a single case can hardly affect conclusions based on the far more extensive studies carried out by me and my collaborators. If bona-fide exceptions are ever found to the multiple-allele theory, where the possibility of technical errors and illegitimacy are ruled out, then one must consider the more plausible possibility of mutation rather than invoke the highly improbable concept of crossing over between tightly linked genes; and no doubt there must be still other possibilities of which we are not aware in the present state of scientific knowledge. While, after Levine's discovery of the first Hr factor, it should have been possible to predict the existence of three Hr factors on the basis of the theory of multiple allelic genes as well as the theory of linked gene triplets, Fisher deserves great credit for his keen insight, which led him to predict the existence of hr¹ and Hr, several years before they were finally found.

In conclusion, the various objections which have been raised by C-D-E workers against the original Rh-Hr notations have now all been answered without difficulty. It is now time for the C-D-E protagonists to answer the criticisms of their nomenclature or to abandon their stubborn position for the good of the subject.

ANALGESIA IN CHILDBIRTH PRIVATE MEMBER'S BILL

Mr. Peter Thorneycroft, M.P., who will introduce into the House of Commons on March 4 a private member's Bill intended to ensure that all midwives are trained in the latest methods of analgesia and are provided with the necessary apparatus for giving it, described the provisions of the Bill at a press conference organized by the National Birthday Trust Fund.

The Bill, which consists of nine clauses, provides that, after three years from its passing, a woman who has not received instruction in accordance with rules framed by the Central Midwives Board in the administration of analgesics to women in childbirth shall not be allowed to practise as a midwife; further, that a woman who may have received such instruction but has not also received such further instruction as may be prescribed by rules framed from time to time by the Board shall not be allowed to practise.

It is declared to be the duty of every local health authority to secure the provision of means to enable midwives so instructed and employed under the National Health Service Act (Part III, Section 23) to administer analgesics to women who desire them. The local health authority is also to ensure that sufficient approved apparatus, facilities for transport, and supplies of drugs are provided and are at all times available for midwives. Those having control or management of a hospital or maternity home are also required to provide such apparatus and drugs. The right of the midwife to administer analgesics is stated in Clause 5, which runs:

"Any certified midwife who has received such instruction in the administration of analgesics to women in childbirth as may from time to time be prescribed by rules framed by the Board shall be entitled to administer, in accordance with any rules framed and any method approved from time to time by the Board, an analgesic to any woman who desires it during childbirth."

It was stated at the press conference that present arrangements for giving this relief varied very greatly from one area to another. Ample provision existed in some places, while in others arrangements were almost non-existent. It was felt that the Bill raised no issue of party politics, and was one in which all women would be interested. The National Birthday Trust Fund, which had worked for twenty-one years for the right of the mother to have relief if she desired it, and if there was no medical reason why she should not receive it, was strongly supporting the Bill, and believed that if it was passed into law it would not be long before all women, whether confined in hospital or at home, would be able to ask for and obtain analgesia.

Lady Rhys-Williams stated that a survey made recently by the Trust Fund revealed that analgesia was given to only 52% of women confined in hospital. Of the 17,000 practising midwives, 7,000 were qualified to give gas-and-air analgesia, and the Bill looked forward to advances in anaesthesia and provided for refresher courses for midwives. Lady Rhys-Williams also said that "trilene" might shortly be approved for use by midwives.

The Bill contains penal clauses whereby midwives giving analgesia without the prescribed instruction will be liable on summary conviction to a penalty not exceeding £10, and to a further penalty of the same amount for each day on which the offence continues after conviction. There are similar penalties for the managers of hospitals or nursing-homes who fail to make the required provision.

Preparations and Appliances

A SIMPLE PORTABLE ANAESTHETIC APPARATUS

Wing Commander R. L. SOPER, senior specialist in anaesthetics, R.A.F., writes: There is a real need for a simple portable apparatus designed primarily for the non-specialist anaesthetist. The one here illustrated operates normally as a gas-and-oxygen apparatus, to which ether or other vapours can be added by means of two Thornton vaporizers. If desired, by means of an air-inlet valve it will act as a simple draw-over

apparatus for trilene-air or ether-air (see the description by Dr. Marrett, *Journal*, 1942, 1, 643). Rebreathing is readily obtained with either technique. The weight of the complete unit is just over 12 lb.

I would like to thank Mr. R. W. Avery for his assistance with the original design, and Mr. E. P. Childerhouse, of Medical and Industrial Equipment, Ltd. (the makers), for help in producing the apparatus.

Reports of Societies

PREVENTIVE PSYCHIATRY

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on Feb. 7, under the chairmanship of Sir ALLEN DALEY, "Preventive Psychiatry" was discussed.

Dr. W. S. MACLAY, Senior Medical Commissioner of the Board of Control, in a brief introduction mentioned one or two projects which were developing. One was the World Federation for Mental Health, which came into existence following the International Congress held in London last August. Another development was the out-patient clinics, which had multiplied since the Mental Treatment Act, 1930, and now numbered 250 for adults and 120 for child guidance, but many more were needed. In 1941 the first disablement rehabilitation officers were appointed. The Ministry of Labour had recognized the value of a liaison between the organization for getting back into industry persons suffering from psychiatric disability and the mental hospitals, out-patient clinics, and social centres which also existed to help them. Dr. MacLAY also mentioned the provisions of the new Criminal Justice Act, especially from the point of view of the prevention of delinquency, and of the National Health Service Act.

Dr. A. TORRIE said that the prevention of psychiatric illness in the Army should start with the recruiting board. Now that the Pulheims system had been introduced he hoped there would be far fewer breakdowns, but the system must be applied with wisdom and discretion. (The Pulheims system was the subject of the opening article in the *Journal* of Jan. 15, p. 83.)

In the early stages of life in the Army instruction should be given in the general principles of mental health. Good leadership and good relations were essential to preventive psychiatry, and the influence which could be exercised by the padre should not be overlooked. The same was true of the industrial community. Here he considered that the family doctor was the key man in prevention, but the help of the clergy, social workers, and of all who were in positions of supervision, including the junior foreman, was to be desired.

Child Guidance

Dr. EMMANUEL MILLER said that child guidance was no new thing. The claim of psycho-analysis was primarily that disturbances in childhood producing neurosis, psychosis, and behaviour disorders lay somewhere in the child-parent relationship. Dr. Miller instanced the question of suckling and its periodicity, and the effect of artificial feeding, and discussed the assistance which psychiatrists and psychologists could give at the mothercraft level. What could the psychiatrist do to help prospective and nursing mothers to understand the significance of the maternal role? Could the psychiatrist come in at that level and make a woman understand the difference between the biological function of maternity and the psychological function of motherliness? Almost any woman could be a mother, relatively few could be motherly. Again, with regard to sex interest and conduct, was there a technique of sex instruction which psychiatrists ought to formulate and hand over to educationists and parents?

What would be the effect of prophylactic psychiatry directed towards the child upon the ultimate incidence of neurosis and psychosis and the like in the adult community? On the theory that all such disorders were produced during the formative months and early years of child life it might be supposed that if it were possible to treat all the childhood difficulties in the community there would presently arise a race of adults free from these disturbances. He could not believe that that would be true. With every phase of mental growth and development new factors entered into the life of the individual. There were new factors at puberty, for example, and also in adult life. No foolproof protection could be obtained by treating children alone. Child psychiatry had the power to produce techniques and methods of handling which would materially reduce adult disturbances, but it would be rash at this stage to say that it had the power to filter them off completely.

Mental Stress in the Future

Dr. C. P. BLACKER asked the audience to consider what kind of mental stress was likely to develop in the future. He discerned two recent trends. A Population Investigation report which would be published shortly would call attention to diminished fertility; increasing use of birth control, especially the use of appliance methods; increasing awareness of the difference between planned and unplanned pregnancies and between wanted and unwanted children; an increasing tendency for couples to plan the size of their families at marriage; and the diminishing size of planned families. This meant a diminution in the numbers of unwanted children. If there was a general movement in favour of small planned families the problem of the future would not be the neglected child but the spoilt child. Parallel with this, the new educational service promised secondary education for all children, which would effect equalization of educational opportunities. Most parents would hope that their sons would be enabled to practise in the professions, and questions would arise about how entry into the professions should be regulated. There would be disappointment for the great majority of boys and girls who, though educated to the same level as the successful ones, would not be eligible for the coveted jobs.

Thus a new mental health problem would arise. On the one hand there would be the wanted child, the object of great solicitude, and on the other there would be a system whereby the aspirations kindled in such children would be thwarted. That was the new problem that would trouble the next generation of psychiatrists. It would mean new stresses, in some ways more troublesome and more provocative of neurosis than the old. The door would be opened much more widely to a self-regarding attitude in which jealousy would take a larger place than it had done in the more happy-go-lucky forms of society to which most of us had been accustomed.

GRANULOMATA OF THE LARGE INTESTINE

A meeting of the Section of Proctology of the Royal Society of Medicine was held on Feb. 9, Mr. C. NAUNTON MORGAN presiding, for a discussion on the subject of granulomata of the large intestine.

Actinomycosis of Rectum and Colon

Mr. ZACHARY COPE said that actinomycosis involving the colon and rectum was a rare condition. In nine cases out of ten it was the anaerobic organism which was concerned, although in many textbooks there was still confusion on this point. He had been able to collect only six cases of actinomycosis of the colon, and in five of these it was excised under the impression that the actual pathological lesion was a carcinoma. Actinomycosis of the rectum, of which he had collected accounts of 40 cases, brought many diagnostic puzzles to the surgeon. The cases could be divided into primary and secondary, "secondary" meaning the invasion of the rectum from above. The diagnosis of primary rectal actinomycosis could be made with certainty only by detection of the fungus in the discharge. The condition might easily simulate malignancy, tuberculosis, or any other chronic inflammation of the rectum. Prognosis had been unfavourable, and although the patient might seem to be cured it was necessary to watch for a year or two before cure could be pronounced with certainty; recurrences sometimes appeared after a long interval.

Secondary actinomycosis usually spread down from the appendix, sometimes from the stomach. A few cases had resulted from perforation of a gastric ulcer, which allowed the organism to escape into the peritoneal cavity and so into the rectum. Symptoms were not characteristic. There might be pus, mucopus, or mucus in the stools, diarrhoea and constipation, suppuration, obstruction of the large bowel, abdominal distension, piles, or fistulae. Sigmoidoscopy was not of much use except in rare cases. He believed that there must be more of these cases than was commonly supposed. In treating patients suffering from actinomycosis in the pelvis up to half a million units of penicillin a day, carried on for many weeks, should be given. It was important to give large doses and to keep up

the administration week after week until the patient was free from symptoms.

Crohn's Disease

Professor G. HADFIELD said that there was still complete ignorance about the cause of Crohn's disease, and possible for that reason its treatment remained uncertain and unsatisfactory. So far as he knew there was no pathological evidence which justified any conclusion regarding its exact aetiology. In an earlier study he and others concluded that during the initial period the intestinal lesion was able completely to repair itself, and that the later main manifestations of the disease were secondary and possibly non-specific complications. That view was founded largely on the pathological evidence afforded by the relatively early cases.

The speaker showed lantern slides of a number of specimens, including the irreparable stage of the "cobble-stone ileum". He also exhibited a diagram illustrating the probable origin and progress of this disease, beginning with a submucous lymphadenoma and then, after the local oedema had reached its maximum, with progressive ulceration and secondary infection increasingly dominating the picture and going on to obstruction and fistulae. He quoted the results, published in 1945 of Garlock and Crohn

	Cases	Post-operative Deaths	Recurrences
Ileo-colostomy, transection and exclusion of lesion	65	0%	13.8%
Primary resection	55	16%	19.5%
Ileo-colostomy, exclusion of lesion followed by resection	25	12%	36.3%

In the 25 cases in the third group it was reported that the lesion and resected loop almost invariably showed advanced healing and little or no inflammation. Unless there was extensive ulceration the initial bowel lesion would repair itself if placed in conditions of complete physiological rest.

Amoebic Granuloma

Mr. R. W. NEVIN said that the importance of intestinal amoebiasis to the surgeon was that the condition might simulate almost any abdominal lesion and if an operation was carried out in unrecognized and unsuspected cases the mortality was very high. It had been stated that this condition was one for surgical diagnosis and medical treatment. Granulomata were most commonly found either in the caecal or the recto-sigmoid region. The condition was very easily confused with carcinoma. Mistakes were frequently made in diagnosis unless this condition was kept in mind. *Entamoeba histolytica* might be demonstrated in the stools or a typical lesion might be shown. On treatment with emetine the granulomata usually disappeared, leaving little scar tissue. The ultimate difficulty in diagnosis lay in the fact that a granuloma and a carcinoma might exist together in the same patient at the same time. The speaker cited some of his personal cases. Among them was a woman, aged 46, who had never been out of the country. She presented symptoms typical of carcinoma of the rectum, in the upper third of which, on examination, a firm fibrous mass was felt. Proctoscopy and sigmoidoscopy revealed no ulcers or abnormalities other than the palpable lesion. A specimen was taken and was returned as granulation tissue. Stools were searched for noeba, but none were found. After giving emetine, however, noeba did appear, and under further treatment the mass disappeared completely.

Individuals with latent or chronic amoebiasis would usually have a secondary anaemia and appear to be in chronic ill-health. It was generally held that a majority of persons suffering from amoebiasis did not present dysenteric symptoms. In about one-third of all cases there were demonstrable lesions which could be seen with the sigmoidoscope.

If all other methods of diagnosis failed, the therapeutic test could be applied. A course of emetine should be given and its effect observed. This might give absolute proof by the production of amoebae in the stools or the relief of symptoms and signs. Treatment was by means of the appropriate anti-amoebic drugs. If this failed in a suspected case, resection might be undertaken and further medical treatment given.

ASSOCIATION OF CLINICAL PATHOLOGISTS

SCIENTIFIC MEETING

The 41st scientific meeting of the Association of Clinical Pathologists was held at Westminster Hospital on Jan. 27, 28, and 29, with Professor R. J. V. PULVERTAFT in the chair.

Dr. F. B. SMITH, in his presidential address, discussed what appeared to be a new syndrome of atypical (septicaemic) tuberculosis with agranulocytosis. He described four adult cases with pyrexia, purpura, and agranulocytosis. Although there was heavy blood-borne bacterial infection as evidenced by dense colonies of mycobacteria in the liver, spleen, and the few lymph nodes found at necropsy, yet there was no histological change typical of tuberculosis and no clear primary focus.

Dr. C. W. TAYLOR described the various virilizing tumours of the ovary and said they fell into two groups: (1) arrhenoblastoma with structures of testicular type (differentiated or embryonic); and (2) lipid-cell tumours of the so-called adrenal-like type. He showed how removal of the tumour resulted in regression of masculinization and a return to a normal menstrual cycle in one month. In two cases full-term pregnancy subsequently occurred followed by lactation. He considered it unwise to accept the virilizing lipid-cell tumour as of heterotopic adrenal origin. Dr. H. R. MAYOR reviewed the series of changes occurring in fat embolism of the brain with large numbers of intravascular fat plugs.

Gastro-enteritis

On Friday Dr. C. GILES described an investigation into the coliform flora in gastro-enteritis. He said that the type of *Bact. coli* was isolated from 94.7% of the faeces of 207 cases of gastro-enteritis, whereas it was only found in 1.8% of 721 controls. Antibody titres were raised in 60% of 41 cases and in only 1.2% of controls. In 55 necropsies the organism was found almost constantly in the gastro-intestinal tract and was isolated occasionally from the mesenteric lymph nodes, the liver, and the spleen. Feeding experiments were unsuccessful except with 10 newborn guinea-pigs; five of these developed diarrhoea and three died, with findings at necropsy similar to those in infants dying from gastro-enteritis.

Dr. JOAN TAYLOR, who had also found such strains (called by her D.433) in sporadic outbreaks of gastro-enteritis, was still sceptical about their pathogenicity.

Dr. GEORGINA M. BONSER had observed in collaboration with Professor M. J. Stewart a series of 57 melanin-forming epidermal tumours. These tumours were classified histologically as squamous papillomas (21), benign calcified epitheliomas (2), and basal-cell (28) and squamous (6) cancers. They were to be distinguished from the true benign and malignant melanomata, which were accepted as being of neurogenic origin. They tended to appear in age groups over 50 years, and to occur more commonly on the face and neck than on the trunk and extremities. There was usually a long history, but they did not metastasize. These tumours were not more malignant than their non-melanin-forming counterparts and responded to the same type of treatment.

Dr. J. HOOGLSTRATEN had compared the *in vitro* growth of leukaemic cells in the serum of a healthy person and in the serum of the leukaemic patient. He said that immature leukaemic cells, although incapable of differentiation *in vivo*, would differentiate or mature *in vitro* when grown in normal human or animal plasma. Fresh blood or plasma transfusions might produce temporary haematological and clinical improvement and even diminution in the size of the enlarged lymph nodes and spleen; reconstituted dried plasma did not have this effect. Leukaemic cells were therefore cultured experimentally, and he showed that these immature myeloblasts and myelocytes were capable of a degree of differentiation *in vitro* resembling that of normal leukopoietic cells, but with the same rate of proliferation and extent of differentiation whether grown in leukaemic or in normal serum. Normal plasma therefore did not exert its influence directly on leukaemic cells but possibly through an intermediary mechanism or another tissue.

Dr. M. C. G. ISRAËLS put forward a strong plea for agreement on the nomenclature of blood and marrow cells. There

was already a measure of agreement in terminology for the white cell series, but the position of the red cell series had been further complicated by the proposals of the American committee, which wished to include the hybrid terms "rubriblast," "rubricyte," "metarubricyte," etc.; the megaloblast was to be called "pernicious anaemia type rubricyte."

It was generally agreed by subsequent speakers that the terms now in use in this country were acceptable and that what was really required to avoid confusion was a standardized description of the cells which were called proerythroblasts, megaloblasts, and normoblasts. It was announced that the association had set up a committee on haematology.

Anaesthetic Deaths

A formal discussion on anaesthetic deaths was opened by Dr. KEITH SIMPSON, who spoke of the group of people who had a slender hold on life and were killed by trivial accidents and stresses. Dr. R. D. TEARE discussed curare and myanescine in this connexion, and Dr. F. E. CAMPS described the pathology of deaths from anoxia. Dr. G. S. W. ORGANE gave the anaesthetist's point of view and suggested that the pathologist was not the best person to investigate anaesthetic deaths, as there was little gross change. He pleaded for an investigation by anaesthetists, who were in a better position to ascertain what procedures had been adopted and whether any fault in technique could be found, so that the administrator could be guided, rather than reprimanded by a coroner. Dr. C. D. COGSWELL, coroner for the county of Middlesex, and himself a doctor and anaesthetist, said that the coroner was not apportioning blame but merely holding an inquiry into the relevant events leading up to an anaesthetic death. Others who took part in the discussion were Professor R. R. MACINTOSH, Dr. I. W. MAGILL, and Dr. W. R. HEDDY.

On Saturday, with Dr. C. J. C. BRITTON in the chair, Dr. J. MURRAY and Drs. E. N. ALLOTT and C. A. HOLMAN described their methods of investigating foetal haemolytic disease with special reference to prevention and treatment. In the discussion which followed, Sir LEONARD PARSONS congratulated the speakers on their results. He showed how the mortality had dropped in the best hands from 50% to about 10%. Dr. W. WEINER reviewed some cases of leukaemia in which he had used replacement transfusion. He had produced some clinical improvement, which was, however, only temporary. Subsequent speakers doubted the wisdom of transfusion in leukaemia, especially in children.

With Professor N. F. MACLAGAN in the chair the final session opened by Dr. M. HYNES, who described his experimental work on the normal iron reserves in man. This was done by giving a man until his rate of regeneration of haemoglobin reached a constant level. The daily absorption of iron from the food in excess of that normally required to replace effete red cells was calculated by the different rates of regeneration of haemoglobin when 6.5 ml. and 20 ml. of blood, respectively, were withdrawn daily after exhaustion of the iron reserves.

Professor E. C. DODDS, after discussing the nomenclature used in steroid chemistry, went on to give an account of the modern method. Almost any woman could give steroids. He mentioned the motherly. Again, with regard to colleagues that many diseases, was there a technique of sex-tic steroid pattern of psychiatrists ought to formulate and hand over the claim that the and parents?

What would be the effect of prophylactic steroids isolated from towards the child upon the ultimate incidence of analyses should psychosis and the like in the adult community and of other that all such disorders were produced during the first months and early years of child life it might be if it were possible to treat all the childhood disturbances. In the community there would presently arise a race of fools from these disturbances. He could not believe that it to be true. With every phase of mental growth and at the meeting new factors entered into the life of the individual. The Psychological Society new factors at puberty, for example, and also, on Feb. 18, when foolproof protection could be obtained by use of the subperitoneal alone. Child psychiatry had the power to prevent the thirty-second and methods of handling which would be quietly in a cinema disturbances, but it would be rash at the iliac fossa. On admission the power to filter them off completely. The uterus was displaced

to the left by a mass at the right side which, on exploration, was found to be a haematoma of the broad ligament. A large-bore rubber drainage tube was inserted extraperitoneally into the haematoma. The patient had a stormy convalescence, during which signs of toxæmia of pregnancy became evident and a stillborn macerated foetus was expelled on the second day. Mr. S. BENDER described a case of appendicitis during pregnancy in which the foetus survived a series of major complications, and Dr. T. REDMAN read a short paper entitled "Descent of the Foetal Head in Late Pregnancy and Labour." Mr. P. MALPAS discussed the limited use of vaginal packing: the treatment of uterine haemorrhage following caesarean section for placenta praevia.

TREATING THE AGED SICK AT HOME

The Medical Society for the Care of the Elderly met at St. Heli Hospital, Carshalton, on Jan. 25. Dr. E. B. BROOKE, medical superintendent of the hospital, read a paper on the domiciliary treatment of the aged sick.
